AFFINE PARIKH AUTOMATA *

Michaël Cadilhac¹, Alain Finkel² and Pierre McKenzie¹

Abstract. The Parikh finite word automaton (PA) was introduced and studied in 2003 by Klaedtke and Rueß. Natural variants of the PA arise from viewing a PA equivalently as an automaton that keeps a count of its transitions and semilinearly constrains their numbers. Here we adopt this view and define the affine PA, that extends the PA by having each transition induce an affine transformation on the PA registers, and the PA on letters, that restricts the PA by forcing any two transitions on the same letter to affect the registers equally. Then we report on the expressiveness, closure, and decidability properties of such PA variants. We note that deterministic PA are strictly weaker than deterministic reversal-bounded counter machines.

Mathematics Subject Classification. 68Q45.

1. Introduction

Klaedtke and Rueß [17] introduced the Parikh automaton as a pair \((A, C)\) where \(C\) is a semilinear subset of \(\mathbb{N}^d\) and \(A\) is a finite automaton over \((\Sigma \times D)\) for \(\Sigma\) a finite alphabet and \(D\) a finite subset of \(\mathbb{N}^d\). The word \(w_1 \ldots w_n \in \Sigma^*\) is accepted by

Keywords and phrases. Automata, semilinear sets, affine functions, counter machines.

(A, C) if A accepts some word \((w_1, \text{vec}_1) \ldots (w_n, \text{vec}_n)\) such that \(\sum \text{vec}_i \in C\). Motivated by verification issues, Klaedtke and Rueß developed the PA as a tool to probe (weak) monadic second-order logic with successor in which the cardinality \(|X|\) of each second-order variable \(X\) is available. They proved their logic undecidable but showed decidability of an existential fragment that was successfully applied to verify the specification of actual hardware circuits.

Klaedtke and Rueß also studied decidability properties of the PA and properties of the language classes defined by the PA [16, 17]. Karianto [15] took up this study further, elaborating on Klaedtke and Rueß’s proofs and considering pushdown automata and constraint sets beyond semilinear. As for tree languages, Klaedtke and Rueß [16] introduced Parikh Tree Automata as top-down tree automata with one global semilinear constraint; at the same time, the related notion of Presburger Tree Automata, which combines bottom-up tree automata and semilinear preconditions about the number of children in a given state, was independently introduced by Zilio and Lugiez [27] and Seidl et al. [22].

Our interest in the PA comes both from its role in the area of verification and from the intricate three-way connection known to exist between automata, descriptive complexity and Boolean circuit complexity (see [23, 24]). Indeed several circuit-based complexity classes within the class LOGCFL (of languages reducible to a context-free language) can be described in a natural way using first-order logic. In such a logic description, the (generalized) quantifiers reflect the properties of the automaton-based model defining the language while the (numerical) predicates reflect the level of uniformity allowed to the circuit families accepting the language. Since semilinearity arises in the study of LOGCFL (see [21]) and since the circuit depth complexity of regular languages is a major open question in complexity theory, the PA is a very appealing computation model with which to experiment in view of possible future applications to complexity theory.

In this paper we introduce three models closely related to the PA and we carry the study of PA themselves somewhat further. This is our first contribution. Informally, each model involves a finite automaton \(A\) and a constraint set \(C \subseteq \mathbb{K}^d\) where \(\mathbb{K}\) is either \(\mathbb{N}\) or \(\mathbb{Q}\):

- **Constrained automata (CA)** with \(d\) transitions are defined to accept a word \(w \in \Sigma^*\) iff \(C\) contains the \(d\)-tuple that records, for some accepting run of \(A\) on \(w\) and for each transition \(t\), the number of occurrences of \(t\) along that accepting run; we will see that the CA merely provides an alternate view of the PA in that the two models define the same language classes.

- **Affine Parikh automata (APA)** generalize PA by allowing each transition to perform an affine transformation on the \(d\)-tuple of PA registers; an APA accepts a word \(w\) iff some accepting run of \(A\) on \(w\) maps the all-zero \(d\)-tuple to a \(d\)-tuple in \(C\).

- **Parikh automata on letters (LPA)** restrict PA by imposing the condition that any transition on \((a, \text{vec}) \in (\Sigma \times D)\) and any transition on \((b, \text{vec}) \in (\Sigma \times D)\) must satisfy \(\text{vec} = \text{vec}\) when \(a = b\).
Our second contribution is the analysis of the closure and decidability properties of these models and their deterministic variants DetPA and DetAPA. We depict the known properties of PA [15–17] together with our new results in Figure 1, where DetLPA is not mentioned because DetLPA and LPA define the same languages.

Our third contribution is the comparison of the language classes that arise. We show that the language \( \{a, b\}^* \cdot \{a^n \#a^n \mid n \in \mathbb{N}\} \) belongs to \( \mathcal{L}_{PA} \setminus \mathcal{L}_{DetPA} \) where these two classes were only proved different in [17]. We show that APA and DetAPA over \( \mathbb{Q} \) can be simulated by APA and DetAPA over \( \mathbb{N} \) and vice versa. Refining [17] slightly, we compare our models with the reversal-bounded counter machines (RBCM) defined by Ibarra [12]. Figure 2 summarizes these and further results.

This paper is organized as follows. Section 2 contains preliminaries and settles notation. Section 3 defines the PA, introduces the equivalent CA, justifies the PA line and DetPA line entries from Figure 1 and compares the PA with Ibarra’s RBCM. Sections 4 and 5 investigate the APA and the LPA respectively, completing the proofs of all remaining entries in Figures 1 and 2. Section 6 concludes with a short discussion.

2. Preliminaries

Let \( \mathbb{Z} \), \( \mathbb{N} \), and \( \mathbb{Q} \) denote the integers, the nonnegative integers, and the rational numbers respectively. We write \( \mathbb{N}^+ \) for \( \mathbb{N} \setminus \{0\} \) and \( \mathbb{Q}^+ \) for the strictly positive rational numbers. We use \( \mathbb{K} \) to denote either \( \mathbb{N} \) or \( \mathbb{Q} \). Let \( d, d' \in \mathbb{N}^+ \). Vectors in \( \mathbb{K}^d \) are noted with a bar on top, e.g., \( \overline{v} \) whose elements are \( v_1, \ldots, v_d \). For \( C \subseteq \mathbb{K}^d \) and \( D \subseteq \mathbb{K}^{d'} \), we write \( C \times D \) for the set of vectors in \( \mathbb{K}^{d+d'} \) which are
Figure 2. Relationships between language classes, sorted vertically by inclusion except for the class CFL of context-free languages delimited by the bell curve; RBCM stands for reversal-bounded counter machine; PAL is the language of pointed palindromes, COPY that of words $w\#w$, $\Sigma ANBN$ that of words $wa^n b^n$, and NSUM is discussed in Proposition 3.14.

(see as) the concatenation of a vector of $C$ and a vector of $D$; we will often use the isomorphism between $K^{d+d'}$ and $K^d \times K^{d'}$. We write $0^d$, or 0 when there is no ambiguity, for the vector with $d$ 0-components, equal to $(0, \ldots, 0) \in K^d$, and $\overline{c}_i \in \{0, 1\}^d$ for the vector having a 1 only in position $i$ and 0 elsewhere. We view $K^d$ as the additive monoid $(K^d, +)$. For a monoid $(M, \cdot)$ and $S \subseteq M$, we write $S^*$ for the monoid generated by $S$, i.e., the smallest submonoid of $(M, \cdot)$ containing $S$.

A monoid morphism from $(M, \cdot)$ to $(N, \circ)$ is a function $h: M \rightarrow N$ such that $h(m_1 \cdot m_2) = h(m_1) \circ h(m_2)$, and, with $e_M$ (resp. $e_N$) the identity element of $M$ (resp. $N$), $h(e_M) = e_N$. Moreover, if $M = S^*$ for some finite set $S$ (and this will always be the case), then $h$ need only be defined on the elements of $S$.

A subset $E \subseteq K^d$ is $K$-definable if it is expressible as a first-order formula which uses the function symbols $+$, $\cdot$, $\lambda_c$ with $c \in K$ corresponding to the scalar multiplication, the order $<$ and constants. More precisely, a subset $E$ of $K^d$ is $K$-definable iff there is such a formula $\phi$ with $d$ free variables, with $(x_1, \ldots, x_d) \in E \iff K \models \phi(x_1, \ldots, x_d)$. Let us remark that $\mathbb{N}$-definable sets are the Presburger-definable sets and they coincide with the semilinear sets [9], i.e., finite unions of linear sets of the form $\{\sum k_i a_i^n | k_i \in \mathbb{N}\}$. Moreover, $Q$-definable sets are the semialgebraic sets$^3$ defined using affine functions, i.e., a set $C \subseteq Q^d$ is $Q$-definable iff it is a finite union of sets of the form:

$$\{\overline{x} \mid f_1(\overline{x}) = \ldots = f_p(\overline{x}) = 0 \land g_1(\overline{x}) > 0 \land \ldots \land g_q(\overline{x}) > 0\},$$

where $f_1, \ldots, f_p, g_1, \ldots, g_q: Q^d \rightarrow Q$ are affine functions (see, e.g., [25], Cor. I.7.8); this shows in particular that over $Q$ the formulas previously described admit quantifier elimination (see also [7]).

$^3$Semialgebraic sets defined using affine functions are sometimes also called semilinear (e.g., [25]). In this paper, we use “semilinear” only for $N$-definable sets.
Let $\Sigma = \{a_1, \ldots, a_n\}$ be an (ordered) alphabet, and write $\varepsilon$ for the empty word. The Parikh image is the morphism $\Phi: \Sigma^* \to \mathbb{N}^n$ defined by $\Phi(a_i) = \overline{c_i}$, for $1 \leq i \leq n$. A language $L \subseteq \Sigma^*$ is said to be semilinear if $\Phi(L) = \{\Phi(w) \mid w \in L\}$ is semilinear. The commutative closure of a language $L$ is defined as the language $c(L) = \{w \mid \Phi(w) \in \Phi(L)\}$. Two words $u, v \in \Sigma^*$ are equivalent under the Nerode relation (of $L$), if for all $w \in \Sigma^*$, $uw \in L \iff vw \in L$. We then write $u \equiv_L v$ (or $u \equiv v$ when $L$ is understood), and write $[u]_L$ for the equivalence class of $u$ w.r.t. the Nerode relation.

We then fix our notation about automata. An automaton is a quintuple $A = (Q, \Sigma, \delta, q_0, F)$ where $Q$ is the finite set of states, $\Sigma$ is an alphabet, $\delta \subseteq Q \times \Sigma \times Q$ is the set of transitions, $q_0 \in Q$ is the initial state, and $F \subseteq Q$ are the final states. Note that no transition is labeled by the empty word. For a transition $t \in \delta$, where $t = (q, a, q')$, we define $\text{From}(t) = q$ and $\text{To}(t) = q'$. Moreover, we define $\mu_A: \delta^* \to \Sigma^*$ to be the morphism defined by $\mu_A(t) = a$ (where in particular $\mu_A(\varepsilon) = \varepsilon$), and we write $\mu$ when $A$ is clear from the context. A path on $A$ is a word $\pi = t_1 \ldots t_n \in \delta^*$ such that $\text{To}(t_i) = \text{From}(t_{i+1})$ for $1 \leq i < n$; we extend $\text{From}$ and $\text{To}$ to paths, letting $\text{From}(\pi) = \text{From}(t_1)$ and $\text{To}(\pi) = \text{To}(t_n)$. We say that $\mu(\pi)$ is the label of $\pi$. A path $\pi$ is said to be accepting if $\text{From}(\pi) = q_0$ and $\text{To}(\pi) \in F$; we let $\text{Run}(A)$ be the language over $\delta$ of accepting paths on $A$. We then define $L(A)$, the language of $A$, as the labels of the accepting paths, i.e., $\mu_A(\text{Run}(A))$.

3. Parikh automata

Let $\Sigma$ be an alphabet, $d \in \mathbb{N}^+$, and $D$ a finite subset of $\mathbb{N}^d$. Following [17], the monoid morphism from $(\Sigma \times D)^*$ to $\Sigma^*$ defined by $(a, \overline{c}) \mapsto a$ is called the projection on $\Sigma$ and the monoid morphism from $(\Sigma \times D)^*$ to $\mathbb{N}^d$ defined by $(a, \overline{c}) \mapsto \overline{c}$ is called the extended Parikh image.

Remark 3.1. Let $\Sigma = \{a_1, \ldots, a_n\}$ and $D \subseteq \mathbb{N}^n$. If a word $\omega \in (\Sigma \times D)^*$ is in $\{(a_i, \overline{c_i}) \mid 1 \leq i \leq n\}^*$, then the extended Parikh image of $\omega$ is the Parikh image of its projection on $\Sigma$.

Definition 3.2 (Parikh automaton [17]). Let $\Sigma$ be an alphabet, $d \in \mathbb{N}^+$, and $D$ a finite subset of $\mathbb{N}^d$. A Parikh automaton (PA) of dimension $d$ over $\Sigma$ is a pair $(A, C)$ where $A = (Q, \Sigma \times D, \delta, q_0, F)$ is a finite automaton over $\Sigma \times D$, and $C \subseteq \mathbb{N}^d$ is a semilinear set. The PA language, written $L(A, C)$, is the projection on $\Sigma$ of the words of $L(A)$ whose extended Parikh image is in $C$. The PA is said to be deterministic (DetPA) if for every state $q \in Q$ and every $a \in \Sigma$, there exists at most one pair $(q', \overline{c}) \in Q \times D$ such that $(q, (a, \overline{c}), q') \in \delta$. We write $L_{PA}$ (resp. $L_{DetPA}$) for the class of languages recognized by PA (resp. DetPA).

We propose an alternative view of the PA which will prove very useful. We note that a PA can be viewed equivalently as an automaton that applies a semilinear constraint on the counts of the individual transitions occurring along its accepting runs.
Definition 3.3 (constrained automaton). A constrained automaton (CA) over an alphabet $\Sigma$ is a pair $(A, C)$ where $A$ is a finite automaton over $\Sigma$ with $d$ transitions, and $C \subseteq \mathbb{N}^d$ is a semilinear set. Its language is $L(A, C) = \mu_A(\text{Run}(A) \mid C)$, where $L \mid C = \{w \in L \mid \Phi(w) \in C\}$. The CA is said to be deterministic (DetCA) if $A$ is deterministic.

Theorem 3.4. CA and PA define the same classes of languages. The same holds in the deterministic case.

Proof. Let $(A, C)$ be a PA (resp. DetPA) of dimension $d$, and let $\delta = \{t_1, \ldots, t_n\}$ be the transitions of $A$. We suppose moreover that $A$ is deterministic – this does not imply the determinism of the PA. Consider the automaton $A'$ which is a copy of $A$ except that the vector part of the transitions is dropped, and note that if $(A, C)$ is a DetPA then $A'$ is deterministic. Suppose that the mapping induced between the transitions of $A$ and $A'$, i.e., $(p, (a, v), q) \mapsto (p, a, q)$, is a bijection. The contribution of a transition $t_i = (p, (a, v_i), q)$ to the extended Parikh image of the label of a run in which it appears is $\overline{v_i}$; thus, knowing how many times $t_i$ is taken in a path is enough to retrieve the value of the extended Parikh image of the label of a path. More precisely, for a path $\pi$ in $A$ and the equivalent path $\pi'$ in $A'$, if we let $\Phi(\pi') = (x_1, \ldots, x_n)$ then the extended Parikh image of $\mu(\pi)$, $\overline{\Phi(\mu(\pi))}$, is $\sum_{i=1}^{n} x_i \times \overline{\Phi(\mu(t_i))}$. Thus, we define $C' \subseteq \mathbb{N}^n$ by $C' = \{(x_1, \ldots, x_n) \mid \sum_{i=1}^{n} x_i \times \overline{\Phi(\mu(t_i))} \in C\}$, and the PA $(A, C)$ has the same language as the CA $(A', C')$, and determinism is preserved.

Now note that the aforementioned bijection exists if no two distinct transitions $t_i, t_j$ are such that $t_i = (p, (a, \overline{v}), q)$ and $t_j = (p, (a, \overline{v}), q)$. So suppose that such $t_i$ and $t_j$ exist, we show how to remove them; iterating this process will lead to a PA with no such pair of transitions. First, we increment the dimension of the PA by adding a 0 component to all the vectors appearing as labels, i.e., each label $(\ell, \overline{v})$ is replaced by $(\ell, (0, \overline{v}))$. Next, we remove $t_i$ and $t_j$ and add the transition $t = (p, (a, \overline{e_d+1}), q)$ where $\overline{e_d+1} \in \{0, 1\}^{d+1}$ has a one only in position $d + 1$. Now note that when $t$ is taken in the new automaton, either $t_i$ or $t_j$ could have been taken in the old one. Thus define the semilinear set $D$ to split the number of times $t$ is taken – which is stored in the $d + 1$-th component – between $t_i$ and $t_j$; for $\overline{v}, c \in \mathbb{N}^d, c \in \mathbb{N}$:

$$(\overline{v}, c) \in D \Leftrightarrow (\exists c_i, c_j \in \mathbb{N}) [c = c_i + c_j \land (\overline{v} + c_i \overline{v_i} + c_j \overline{v_j}) \in C].$$

This preserves the language of the PA and does not affect determinism.

For the reverse direction, let $(A, C)$ be a CA (resp. DetCA). Define $A'$ as the automaton $A$ in which each transition $t = (p, a, q)$ is replaced by a transition $(p, (a, \Phi(t)), q)$. Now let $\pi$ be a path in $A$ and $\pi'$ be the corresponding path in $A'$, the construction is such that $\overline{\Phi(\mu(\pi'))} = \overline{\Phi(\pi)}$, thus $(A', C)$ is a PA with the same language as $(A, C)$, and the determinism of $A$ is preserved. \qed
3.1. On the expressiveness of Parikh automata

The constrained automaton characterization of PA helps deriving pumping-style necessary conditions for membership in \( \mathcal{L}_{PA} \) and in \( \mathcal{L}_{DetPA} \):

Lemma 3.5. Let \( L \in \mathcal{L}_{PA} \). There exist \( p, \ell \in \mathbb{N}^+ \) such that any \( w \in L \) with \( |w| \geq \ell \) can be written as \( w = uvxz \) where:

(1) \( 0 < |v| \leq p, |x| > p, \) and \( |uvxv| \leq \ell \);

(2) \( uv^2xz \in L \) and \( uvx^2z \in L \).

Proof. Let \((A, C)\) be a CA of language \( L \). Let \( p \) be the number of states in \( A \) and \( m \) be the number of elementary cycles \( (i.e., \) cycles in which no state except the start state occurs twice) in the underlying multigraph of \( A \). Finally, let \( \ell = p \times (2m + 1) \).

Now, let \( w \in L \) such that \( |w| \geq \ell \) and \( \pi \in \text{Run}(A)_C \) such that \( \mu(\pi) = w \). Write \( \pi \) as \( \pi_1 \ldots \pi_{2m+1} \pi' \) where \( |\pi_i| = p \). By the pigeonhole principle, each \( \pi_i \) contains an elementary cycle, and thus, there exist \( 1 \leq i, j \leq 2m + 1 \) with \( i + 1 < j \) such that \( \pi_i \) and \( \pi_j \) share the same elementary cycle \( \eta \) labeled with a word \( v \). Thus \( \pi \) can be written as \( \rho_1 \eta \rho_2 \eta \rho_3 \), such that, with \( u = \mu(\rho_1), x = \mu(\rho_2), \) and \( z = \mu(\rho_3) \), we have condition (1). Moreover, \( \rho_1 \eta \rho_2 \eta \rho_3 \) and \( \rho_1 \rho_2 ^2 \eta \rho_3 \) are two accepting paths the Parikh images of which are in \( C \), thus their labels, \( uv^2xz \) and \( uvx^2z \) respectively, are in \( L \), showing condition (2). \( \square \)

A similar argument leads to a stronger property for the languages of \( \mathcal{L}_{DetPA} \):

Lemma 3.6. Let \( L \in \mathcal{L}_{DetPA} \). There exist \( p, \ell \in \mathbb{N}^+ \) such that any \( w \) over the alphabet of \( L \) with \( |w| \geq \ell \) can be written as \( w = uvxz \) where:

(1) \( 0 < |v| \leq p, |x| > p, \) and \( |uvxv| \leq \ell \);

(2) \( uv^2x, uvxv, \) and \( uvx^2 \) are equivalent under the Nerode relation of \( L \).

Proof. Let \((A, C)\) be a DetCA of language \( L \subseteq \Sigma^* \). We may suppose that \( A \) is complete, as \( \text{Run}(A) \) is essentially unchanged when adding a sink state to \( A \). Let \( p \) be the number of states in \( A \) and \( m \) be the number of elementary cycles \( (i.e., \) cycles in which no state except the start state occurs twice) in the underlying multigraph of \( A \). Finally, let \( \ell = p \times (2m + 1) \).

Now, let \( w \in \Sigma^{\geq \ell} \) and let \( \pi \) be the path traced by \( w \) in \( A \), which exists as \( A \) is complete. Write \( \pi \) as \( \pi_1 \ldots \pi_{2m+1} \pi' \) where \( |\pi_i| = p \). By the pigeonhole principle, each \( \pi_i \) contains an elementary cycle, and thus, there exist \( 1 \leq i, j \leq 2m + 1 \) with \( i + 1 < j \) such that \( \pi_i \) and \( \pi_j \) share the same elementary cycle \( \eta \) labeled with a word \( v \). Thus \( \pi \) can be written as \( \rho_1 \eta \rho_2 \eta \rho_3 \), such that, with \( u = \mu(\rho_1), x = \mu(\rho_2), \) and \( z = \mu(\rho_3) \), we have condition (1). Moreover, \( uv^2x, uvxv, \) and \( uvx^2 \) trace the paths \( \rho_1 \eta \rho_2 \rho_3, \rho_1 \rho_2 \eta \rho_3, \) and \( \rho_1 \rho_2 \eta \rho_3 \), respectively, in \( A \). Those paths all go from the initial state to the same state \( q \) and have the same Parikh image. Thus let \( \pi'' \) be a path in \( A \) from \( q \) with some label \( y \), then \( uv^2xy \in L(A, C) \) iff \( \pi'' \) ends in a final state and \( \Phi(\rho_1 \eta \rho_2 \pi'') \in C \). But since \( \Phi(\rho_1 \eta \rho_2 \pi'') = \Phi(\rho_1 \rho_2 \eta \pi'') = \Phi(\rho_1 \rho_2 \eta \pi'') \), this is the case iff \( uvxy \in L \) and iff \( uvx^2y \in L \), showing condition (2). \( \square \)
We apply Lemma 3.5 to the language COPY, defined as \( \{w\#w \mid w \in \{a, b\}^*\} \), as follows:

**Proposition 3.7.** \( \text{COPY} \not\in \mathcal{L}_{\text{PA}} \).

**Proof.** Suppose \( \text{COPY} \in \mathcal{L}_{\text{PA}} \). Let \( \ell, p \) be given by Lemma 3.5, and consider \( w = (a^pb)^\ell \#(a^pb)^\ell \in \text{COPY} \). Lemma 3.5 states that \( w = uvxz \) where \( uvx \) lays in the first half of \( w \), and \( s = w^2xz \in \text{COPY} \). Note that \( x \) contains at least one \( b \). Suppose \( v = a^i \) for \( 1 \leq i \leq p \), then there is a sequence of \( a \)'s in the first half of \( s \) unmatched in the second half. Likewise, if \( v \) contains a \( b \), then \( s \) has a sequence of \( a \)'s between two \( b \)'s unmatched in the second half. Thus \( s \not\in \text{COPY} \), a contradiction. Hence \( \text{COPY} \not\in \mathcal{L}_{\text{PA}} \). \( \square \)

As Klaedtke and Rueß show using closure properties, \( \text{DetPA} \) are strictly weaker than PA. The thinner grain of Lemma 3.6 suggests explicit languages that witness the separation of \( \mathcal{L}_{\text{DetPA}} \) from \( \mathcal{L}_{\text{PA}} \). Indeed, let \( \text{EQUAL} \subseteq \{a, b, \#\}^* \) be the language \( \{a, b\}^* \cdot \{a^n \# a^n \mid n \in \mathbb{N}\} \), we have:

**Proposition 3.8.** \( \text{EQUAL} \in \mathcal{L}_{\text{PA}} \setminus \mathcal{L}_{\text{DetPA}} \).

**Proof.** We omit the proof that \( \text{EQUAL} \in \mathcal{L}_{\text{PA}} \). Now, suppose \( \text{EQUAL} \in \mathcal{L}_{\text{DetPA}} \), and let \( \ell, p \) be given by Lemma 3.6. Consider \( w = (a^pb)^\ell \). Lemma 3.6 then asserts that a prefix of \( w \) can be written as \( w_1 = uvx \), and that \( w_2 = w^2x \) verifies \( w_1 \equiv w_2 \). As \( |x| > p \), \( x \) contains a \( b \). Let \( k \) be the number of \( a \)'s at the end of \( w_1 \). Suppose \( v = a^i \) for \( 1 \leq i \leq p \), then \( w_2 \) ends with \( k - i < k \) letters \( a \). Thus \( w_1 \# a^k \in \text{EQUAL} \) and \( w_2 \# a^k \not\in \text{EQUAL} \), a contradiction. Suppose then that \( v = a^i b a^k \), with \( 0 \leq i + k < p \). Then \( w_2 \) ends with \( p - i > k \) letters \( a \), and similarly, \( w_1 \neq w_2 \), a contradiction. Thus \( \text{EQUAL} \not\in \mathcal{L}_{\text{DetPA}} \). \( \square \)

For comparison, we mention another line of attack for the study of \( \mathcal{L}_{\text{DetPA}} \), derived from an argument used by Klaedtke and Rueß to show that \( \text{PAL} = \{w\#w^R \mid w \in \{a, b\}^+\} \), where \( w^R \) is the reversal of \( w \), is not in \( \mathcal{L}_{\text{PA}} \).

**Lemma 3.9.** Let \( L \in \mathcal{L}_{\text{DetPA}} \). There exists \( c > 0 \) such that \( |\{[w]_L \mid w \in \Sigma^n\}| \in O(n^c) \).

**Proof.** Let \( (A, C) \) be a DetCA of language \( L \subseteq \Sigma^* \) where we suppose \( A \) complete, as this leaves \( \text{Run}(A) \) essentially unchanged. For \( w \in \Sigma^* \), write \( \pi(w) \) for the unique path in \( A \) labeled \( w \) and starting with the initial state. Let \( \sim \) be the equivalence relation on \( \Sigma^* \) defined by \( u \sim v \) iff \( \Phi(\pi(u)) = \Phi(\pi(v)) \land \text{To}(\pi(u)) = \text{To}(\pi(v)) \). Then this relation refines \( \equiv_L \) by \( u, v \in \Sigma^* \) such that \( u \sim v \), and let \( w \in \Sigma^* \) such that \( uwL \), then \( \pi(uw) \in \text{Run}(A) \big|_C \), thus the same holds for \( \pi(vw) \), implying that \( vwL \). Moreover, the number of equivalence classes of \( \sim \) for a given word length is polynomial in the word length (e.g., [20], p. 41).

**Proposition 3.10.** Let \( L = \{w \in \{a, b\}^* \mid w_i = b\} \), where \( w_i \) is the \( i \)-th letter of \( w \). Then \( L \in \mathcal{L}_{\text{PA}} \setminus \mathcal{L}_{\text{DetPA}} \).
**Proof.** We omit the proof that $L \in \mathcal{L}_{PA}$; the main point is simply to guess the position of the $b$ referenced by $|w|_{a}$. On the other hand, let $n > 0$ and $u, v \in \{a, b\}^{n}$ such that $|u|_{a} = |v|_{a} = \frac{n}{2}$ and there exists $p \in \{\frac{n}{2}, \ldots, n\}$ with $u_{p} \neq v_{p}$. Let $w = a^{p}b^{\frac{n}{2}}$, then $(uw)|_{uw|_{a}} = (uw)|_{u|_{a}} + |w|_{a} = (uw)_{p} = u_{p}$, and similarly, $(vw)|_{vw|_{a}} = v_{p}$. This implies $uw \not\in L$ if $vw \in L$, thus $u \neq v$. Then for $0 \leq i \leq \frac{n}{2}$, define $E_{i} = \{a^{\frac{n}{2}}-ib^{z} | z \in \{a, b\}^{\frac{n}{2}} \land |z|_{a} = i\}$. For any $u, v \in \bigcup E_{i}$ with $u \neq v$, the previous discussion shows that $u \neq v$. Thus $|\{(w)_{L} | w \in \{a, b\}^{n}\}| \geq \bigcup_{i=0}^{2} E_{i} = \sum_{i=0}^{2} |E_{i}| = \sum_{i=0}^{2} (\frac{n}{2}) = 2^{\frac{n}{2}} \not\in O(n^{O(1)})$. Lemma 3.9 then implies that $L \not\in \mathcal{L}_{DetPA}$. □

Finally, let us recall that a language $L \subseteq \Sigma^{*}$ is said to be bounded if there exist $n > 0$ and $w_{1}, \ldots, w_{n} \in \Sigma^{+}$ such that $L \subseteq w_{1}^{*} \ldots w_{n}^{*}$. For a given class of languages, we say that it is Parikh-bounded if for any $L$ in the class there exists a bounded language $L'$ in the class with $L' \subseteq L$ and $\Phi(L) = \Phi(L')$. This property is known to hold for regular [19] and context-free languages [2] (the latter recently reworked in [8]).

**Proposition 3.11.** $\mathcal{L}_{PA}$ is Parikh-bounded.

**Proof.** Let $(A, C)$ be a constrained automaton, where $\delta$ is the transition set of $A$. Note that $\text{Run}(A)$ is regular, thus, as mentioned, we can find a bounded regular language $R \subseteq \text{Run}(A)$ such that $\Phi(R) = \Phi(\text{Run}(A))$. In particular, $\Phi(R|_{C}) = \Phi(\text{Run}(A)|_{C})$. Closure under morphism of $\mathcal{L}_{PA}$ and of bounded languages implies that $L' = \mu(R|_{C})$ is a bounded language of $\mathcal{L}_{PA}$ included in $L(A, C)$. Moreover, $\Phi(L(A, C)) = \Phi(\mu(R|_{C}))$, and thus, equals $\Phi(L')$. □

### 3.2. Parikh automata and reversal-bounded counter machines

Klaedtke and Rueß noticed in [16] that Parikh automata recognize the same languages as reversal-bounded counter machines, a model introduced by Ibarra [12]:

**Definition 3.12** (reversal-bounded counter machine [12]). A one-way, $k$-counter machine $M$ is a 5-uple $(Q, \Sigma, \delta, q_{0}, F)$ where $Q$ is a finite set of states, $\Sigma$ is an alphabet, $\delta \subseteq Q \times (\Sigma \cup \{\uparrow\}) \times \{0, 1\}^{k} \times Q \times \{S, R\} \times \{-1, 0, +1\}^{k}$ is the transition function, $q_{0} \in Q$ is the initial state and $F \subseteq Q$ is the set of final states. Moreover, we suppose $\uparrow \not\in \Sigma$. The machine is deterministic if for any $(p, \ell, \overline{\tau})$, there exists at most one $(q, h, \overline{\tau})$ such that $(p, \ell, \overline{\tau}, q, h, \overline{\tau}) \in \delta$. On input $w$, the machine starts with a read-only tape containing $w \uparrow$, and its head on the first character of $w$. Let $c_{i}$ be the value of the $i$-th counter, then a transition $(p, \ell, \overline{\tau}, q, h, \overline{\tau}) \in \delta$ is taken if the machine is in state $p$, reading character $\ell$, and $c_{i} = 0$ if $x_{i} = 0$ and $c_{i} > 0$ if $x_{i} = 1$, for all $i$. The machine then enters state $q$, its head is moved to the right iff $h = R$, and $\overline{\tau}$ is added to the counters. If the head falls off the tape, or if a counter turns negative, the machine rejects. A word is accepted if an execution leads to a final state. The machine is reversal-bounded (RBCM) if there exists an integer $r$ such that any accepting run changes between increments and decrements.
of the counters a (bounded) number of times less than \( r \). We write \( \text{DetRBCM} \) for deterministic RBCM. We write \( \mathcal{L}_{\text{RBCM}} \) (resp. \( \mathcal{L}_{\text{DetRBCM}} \)) for the class of languages recognized by RBCM (resp. \( \text{DetRBCM} \)).

In [16], Section A.3, it is shown that PA have the same expressive power as (nondeterministic) RBCM. Although Fact 30 of [16], on which the authors rely to prove that \( \mathcal{L}_{\text{RBCM}} \subseteq \mathcal{L}_{\text{PA}} \), is technically false as stated,\(^4\) the small gap there can be fixed so that:

**Proposition 3.13** ([16]). \( \mathcal{L}_{\text{PA}} = \mathcal{L}_{\text{RBCM}} \).

**Proof.** We sketch \( \mathcal{L}_{\text{RBCM}} \subseteq \mathcal{L}_{\text{PA}} \) for completeness and reprove \( \mathcal{L}_{\text{PA}} \subseteq \mathcal{L}_{\text{RBCM}} \) to extract a more precise structure on the constructed RBCM – this will prove useful when comparing the notion of determinism in both models.

\( \mathcal{L}_{\text{RBCM}} \subseteq \mathcal{L}_{\text{PA}} \). First, it is known [12] that any RBCM language can be expressed as an RBCM which makes at most one change between increment and decrement on each of its counters. Then a counter can be seen as being in one of three different states: (1) never incremented, (2) incremented but never decremented, (3) decremented. When a counter is in state (1), we may simulate the behavior of the RBCM with the counter set to zero. Similarly, when a counter is in state (2), we may simulate the behavior of the RBCM with this counter set to a nonzero value. Lastly, when in state (3), we may guess at some point that the counter reached zero, and act for the rest of the execution as if the counter is actually zero (thus not making any modification to this counter). Now, when in states (1) and (2), the behavior of the RBCM w.r.t. the counter can be simulated using a finite automaton; in state (3), the guess can be taken with a finite automaton, but we must check that the guess was taken at the right moment. Thus we use a PA to count the number of increments and decrements, and we check at the end of the computation that the latter is no greater than the former, and that these are equal iff the counter has been guessed to be zero at some point. Finally, the transitions between the different states can be made knowing only the transitions of the RBCM. This gives the required PA for the RBCM.

\( \mathcal{L}_{\text{PA}} \subseteq \mathcal{L}_{\text{RBCM}} \). Let \((A, C)\) be a CA, where \( A = (Q, \Sigma, \delta, q_0, F) \) and let \( \delta = \{t_1, \ldots, t_k\} \). We define a RBCM of the same language in two steps. (1). First, let \( M \) be the \( k \)-counter machine \((Q \cup \{q_f\}, \Sigma, \zeta, q_0, q_f)\), where \( q_f \not\in Q \) and \( \zeta \) is defined by:

\[
\zeta = \bigcup_{\pi \in \{0, 1\}^k} \left\{ \left( \text{From}(t_i), \mu(t_i), \pi, \text{To}(t_i), R, e_i \right) \middle| 1 \leq i \leq k \right\} \bigcup \bigcup_{\pi \in \{0, 1\}^k} \left\{ \left( q, \pi, q_f, S, 0 \right) \middle| q \in F \right\}.
\]

---

\(^4\)Fact 30 of [16] states the following. Consider a RBCM \( M \) which, for any counter, changes between increment and decrement only once. Let \( M' \) be \( M \) in which negative counter values are allowed and the zero-tests are ignored. Then a word is claimed to be accepted by \( M \) iff the run of \( M' \) on the same word reaches a final state with all its counters nonnegative. A counter-example is the following. Take \( A \) to be the minimal automaton for \( a^*b \), and add a counter for the number of \( a \)'s that blocks the transition labeled \( b \) unless the counter is nonzero. This machine recognizes \( a^+b \). Then by removing this test, the machine now accepts \( b \).
This machine does not make any test, and accepts (in $q_f$) precisely the words accepted by $A$. Moreover, the state of the counters in $q_f$ is the Parikh image of the path taken (in $A$) to recognize the input word. (2) We then refine $M$ to check that the counter values belong to $C$. We note that we can do that as a direct consequence of the proof of [13], Theorem 3.5, but this proof relied on nontrivial algebraic properties of systems $M\overline{f} = \overline{b}$, where $M$ is a matrix, $\overline{f}$ are unknowns, and $\overline{b}$ is a vector; we present here a proof based on a logical characterization of semilinear sets. Recall that $C$ can be expressed as a quantifier-free first-order formula which uses the function symbol $+$, the congruence relations $\equiv_i$, for $i \geq 2$, and the order relation $<$ (see, e.g., [6]). So let $C$ be given as such formula $\phi_C$ with $k$ free variables. Let $\phi_C$ be put in disjunctive normal form. The machine $M$ then tries each and every clause of $\phi_C$ for acceptance. First, note that a term can be computed deterministically with a number of counters and reversals which depends only on its size. For instance, computing $c_i + c_j$ requires two new counters $x, y$: $c_i$ is decremented until it reaches 0, while $x$ and $y$ are incremented, so that their value is $c_i$, now $y$ is decremented until it reaches 0 while $c_i$ is incremented back to its original value, finally the same process is applied with $c_j$, and as a result $x$ is now $c_i + c_j$. Second, note that any atomic formula $(t_1 < t_2$ or $t_1 \equiv t_2)$ can be checked by a DetRBCM: for $t_1 < t_2$, compute $x_1 = t_1$ and $x_2 = t_2$, then decrement $x_1$ and $x_2$ until one of them reaches 0, if the first one is $x_1$, then the atomic formula is true, and false otherwise; for $t_1 \equiv t_2$, a simple automaton-based construction depending on $i$ can decide if the atomic formula is true. Thus, a DetRBCM can decide, for each clause, if all of its atomic formulas (or negation) are true, and in this case, accept the word. This process does not use the read-only head, and uses a number of counters and a number of reversals that depend only on the length of $\phi_C$.

Further, we study how the notion of determinism compares in the two models. Let $NSUM = \{a^m \Diamond b^{m_1} \# b^{m_2} \# \ldots \# b^{m_n} \# c^{m_1 + \ldots + m_n} \mid k \geq n \geq 0 \land m_i \in \mathbb{N}\}$: the number of $a$’s is the number of $m_i$’s to sum to get the number of $c$’s. Note that NSUM is not context-free. Then:

**Proposition 3.14.** $\mathcal{L}_{DetPA} \subseteq \mathcal{L}_{DetRBCM}$ and $NSUM \in \mathcal{L}_{DetRBCM} \setminus \mathcal{L}_{DetPA}$.

**Proof.** The inclusion $\mathcal{L}_{DetPA} \subseteq \mathcal{L}_{DetRBCM}$ follows from the Proof of Proposition 3.13, as the resulting RBCM is deterministic if the given CA is.

We now show that $NSUM \in \mathcal{L}_{DetRBCM} \setminus \mathcal{L}_{DetPA}$. We omit the fact that $NSUM \in \mathcal{L}_{DetRBCM}$. Now suppose $(A, C)$ is a DetPA such that $L(A, C) = NSUM$, with $A = (Q, \Sigma \times D, \delta, q_0, F)$. As $(A, C)$ is a DetPA, $A$ is deterministic – it is indeed deterministic with respect to the first component of the labels. We may suppose that the projection on $\Sigma$ of $L(A)$ is a subset of $a^* \Diamond (b^* \#)^* b^* \Diamond c^*$, so that there exist $k \geq 0, q_1, \ldots, q_k \in Q$, and $j \in \{0, \ldots, k\}$ such that $(q_i, (a, c^k), q_{i+1}) \in \delta$, for $0 \leq i < k$ and some $c^k$’s, and $(q_k, (a, c^k), q_j) \in \delta$. Moreover, we may suppose that no other transition points to one of the $q_i$’s, and that all transitions $t = (q_i, (\ell, \overline{c}), q) \in \delta$ such that $q \notin \{q_0, \ldots, q_k\}$ are with $\ell = \Diamond$: let $T$ be the set of all
such transitions $t$. Graphically, $A$ looks like:

$$
\begin{array}{c}
q_0 \\
\downarrow t \\
(b^*\#)^*b^* \heartsuit^* c^*
\end{array}
$$

We define $|T|$ DetPA such that the union of their languages is $\text{SUMN} = \{\heartsuit w a^n \mid a^n \heartsuit w \in \text{NSUM}\}$, that is, the strings of NSUM with $a^n$ pushed at the end. For $t \in T$, define $A_t$ as the automaton similar to $A$ but which starts with the transition $t$ and delay the first part of the computation until the very end; graphically, $A_t$ is:

$$
\begin{array}{c}
q_0 \\
\downarrow t \\
(b^*\#)^*b^* \heartsuit^* c^*
\end{array}
$$

Formally, $A_t = (Q \cup \{q'_0\}, \Sigma \times D, \delta_t, q'_0, \{\text{From}(t)\})$ where $q'_0$ is a fresh (i.e., new) state and:

$$
\delta_t = (\delta \setminus T) \cup \{(q'_0, \mu(t), \text{To}(t))\} \cup \{(q_f, (\heartsuit, \emptyset), q_0) \mid q_f \in F\}.
$$

Now for $\omega \in L(A)$, let $t$ be the transition labeled $\heartsuit$ taken when $A$ reads $\omega$, and let $\omega = \omega_1 \mu(t) \omega_2$. Then $\mu(t) \omega_2(\heartsuit, \emptyset) \omega_1 \in L(A_t)$, and this word has the same extended Parikh image as $\omega$. Thus we have that $\bigcup_{t \in T} L(A_t, C) = \text{SUMN}$, and if NSUM $\in \mathcal{L}_{\text{DetPA}}$, then SUMN $\in \mathcal{L}_{\text{DetPA}}$, as $\mathcal{L}_{\text{DetPA}}$ is closed under union (see Fig. 1). We now show that SUMN $\notin \mathcal{L}_{\text{DetPA}}$, thus leading to a contradiction showing the result. Suppose SUMN $\in \mathcal{L}_{\text{DetPA}}$ and let $\ell, p$ be given by Lemma 3.6 for SUMN. Consider $w = \heartsuit (b^p \#)^\ell$. Lemma 3.6 then asserts that a prefix of $w$ can be written as $w_1 = uvxv$, and that $w_2 = uv^2x$ verifies $w_1 \equiv w_2$. As $|x| > p$ and $v$ is nonempty, $x$ contains a $\#$; moreover, $v$ does not contain $\heartsuit$. Let $s = |w_1|_\# = |w_2|_\#$ and let $n_i$ be the number of $b$’s before the position of the $s$-th $\#$ in $w_i$, $i = 1, 2$. Suppose $v \in b^+$, then $n_1 < n_2$, thus $w_1 \heartsuit v^{n_1} \heartsuit a^* \in \text{SUMN}$.
and \( w_2 \cup \alpha \cup a^* \not\in \text{SUMN} \), a contradiction. Suppose then that \( v = b^i \# b^j \), with \( 0 \leq i + j < p \). Similarly, as \( i + j < p \), \( n_2 < n_1 \), and again, \( w_1 \neq w_2 \), a contradiction. Thus \( \text{SUMN} \not\in \mathcal{L}_{\text{DetPA}} \). □

The parallel drawn between (Det)PA and (Det)RBCM allows transferring some RBCM and DetRBCM results to PA and DetPA. An example is a consequence of the following lemma proved in 2011 by Chiniforooshan et al. [5] for the purpose of showing incomparability results between different models of reversal-bounded counter machines:

**Lemma 3.15** ([5]). Let a DetRBCM express \( L \subseteq \Sigma^* \). Then there exists \( w \in \Sigma^* \) such that \( L \cap w \Sigma^* \) is a nontrivial regular language.

Using this lemma, variants of the language EQUAL from Proposition 3.8 can be shown outside \( \mathcal{L}_{\text{DetPA}} \). For instance, for \( \Sigma = \{a, b\} \), \( \Sigma \text{ANBN} = \Sigma^* \cdot \{a^n b^n \mid n \in \mathbb{N}^+\} \) is such that any \( w \in \Sigma^* \) makes \( \Sigma \text{ANBN} \cap w \Sigma^* \) nonregular. Although Lemma 3.15 thus gives languages in \( \mathcal{L}_{\text{PA}} \setminus \mathcal{L}_{\text{DetPA}} \), Lemma 3.15 seemingly does not apply to EQUAL itself since \( \text{EQUAL} \cap \# \{a, b, \#\}^* = \{\#\} \) is regular.

### 3.3. On decidability and closure properties of Parikh automata

In this section we justify the PA and DetPA line entries in Figure 1. The known decidability results depicted there (in boldface) are from [12, 17], and Karianto [15] provided detailed proofs.

**Proposition 3.16.** (1) Finiteness is decidable for PA; (2) inclusion is decidable for DetPA and undecidable for PA; (3) regularity is undecidable for PA.

**Proof.**

(1), (2) These decidability properties follow directly from the same properties for RBCM and DetRBCM [14], the effective equivalence between PA and RBCM (Prop. 3.13), and the effective inclusion of \( \mathcal{L}_{\text{DetPA}} \) in \( \mathcal{L}_{\text{DetRBCM}} \) (Prop. 3.14).

(3) This follows from a theorem of [11], which states the following. Let \( C \) be a class of languages closed under union and under concatenation with regular languages. Let \( P \) be a predicate on languages true of every regular language, false of some languages, preserved by inverse rational transduction, union with \( \{\varepsilon\} \) and intersection with regular languages. Then \( P \) is undecidable in \( C \). Obviously, \( L_{\text{PA}} \) satisfies the hypothesis for \( C \). Moreover, “being regular in \( L_{\text{PA}} \)” is a predicate satisfying the hypothesis for \( P \). Thus, regularity is undecidable for PA. □

We now turn to closure properties:

**Proposition 3.17.** (1) \( \mathcal{L}_{\text{DetPA}} \) is not closed under concatenation; (2) \( \mathcal{L}_{\text{DetPA}} \) is not closed under nonerasing morphisms; (3) both \( \mathcal{L}_{\text{PA}} \) and \( \mathcal{L}_{\text{DetPA}} \) are closed under commutative closure; (4) neither \( \mathcal{L}_{\text{PA}} \) nor \( \mathcal{L}_{\text{DetPA}} \) is closed under starring.
Proof.

(1) The language \( \text{EQUAL} \) separating \( \mathcal{L}_{\text{DetPA}} \) from \( \mathcal{L}_{\text{PA}} \) is the concatenation of a regular language and a language of \( \mathcal{L}_{\text{DetPA}} \), implying the nonclosure under concatenation.

(2) We note that any language of \( \mathcal{L}_{\text{PA}} \) is the image by a nonerasing morphism of a language in \( \mathcal{L}_{\text{DetPA}} \). Indeed, say \((A, C)\) is a CA and let \( B \) be the deterministic automaton of language \( \text{Run}(A) \) defined as a copy of \( A \) in which the transition \( t \) is relabeled \((i.e., (p, a, q) \rightsquigarrow (p, (p, a, q), q)) \). Then \((B, C)\) is a DetCA such that \( L(A, C) = \mu_A(L(B, C)) \). This implies the nonclosure of \( \mathcal{L}_{\text{DetPA}} \) under nonerasing morphisms.

(3) Let \( \Sigma = \{a_1, \ldots, a_n\}, L \subseteq \Sigma^* \) a semilinear language, and \( C = \Phi(L) \). Define \( A \) to be an automaton with one state, initial and final, with \( n \) loops, the \( i \)-th labeled \((a_i, i) \in \Sigma \times \{i\}_{1 \leq i \leq n} \). Then \( c(L) = L(A, C) \). This implies that both \( \mathcal{L}_{\text{PA}} \) and \( \mathcal{L}_{\text{DetPA}} \) are closed under commutative closure, as both are classes of semilinear languages [17].

(4) We show that the starring of \( L = \{a^n b^n \mid n \in \mathbb{N}\} \) is not in \( \mathcal{L}_{\text{PA}} \). Suppose \( L^* \in \mathcal{L}_{\text{PA}} \), and let \( w = (a^p b^p)^\ell \), where \( \ell, p \) are given by Lemma 3.5. The same lemma asserts that \( w = u w v v z \), such that, in particular, \( wv^2 z \) and \( wvx^2 z \) are in \( L^* \). Now suppose \( v = a^i \) for some \( i \leq p \). Then \( uv^2 x \) contains \( a^{p+i} b^p \) with no more \( b \)'s on the right. Thus \( uv^2 x \notin L^* \). The case for \( v = b^i \) is similar. Now suppose \( v = a^i b^j \) with \( i, j > 0 \). Then \( uv^2 x \) contains \( a^i b^j a^i b^p \ldots \), but \( i < p \), thus \( uv^2 x \notin L^* \). The case \( v = b^i a^j \) is similar. Thus \( L^* \notin \mathcal{L}_{\text{PA}} \). \( \square \)

Remark 3.18. Baker and Book [1] already note, in different terms, that if \( \mathcal{L}_{\text{PA}} \) were closed under starring, it would be an intersection closed full AFL containing \( \{a^n b^n \mid n \geq 0\} \), and so would be equal to the class of Turing-recognizable languages. Thus \( \mathcal{L}_{\text{PA}} \) is not closed under starring.

4. AFFINE PARIKH AUTOMATA

A PA of dimension \( d \) can be viewed as an automaton in which each transition updates a vector \( \overline{v} \) of \( \mathbb{N}^d \) using a function \( \overline{v} \leftarrow \overline{v} + \overline{a} \) where \( \overline{a} \) depends only on the transition. At the end of an accepting computation, the word is accepted if \( \overline{v} \) belongs to some semilinear set. We propose to generalize the updating function to an affine function. We start by defining the model, and show that defining it over \( \mathbb{N} \) is as general as defining it over \( \mathbb{Q} \). We study the expressiveness of this model and show it is strictly more powerful than PA. We then study its (non)closure properties and related decidability problems, leading to the observation that the model lacks some desirable properties — e.g., properties usually needed for any real-world application.

Let \( d, d' > 0 \). In the following, we consider the vectors in \( \mathbb{K}^d \) to be column vectors. A function \( f : \mathbb{K}^d \rightarrow \mathbb{K}^{d'} \) is a (total) affine function if there exist a matrix \( M \in \mathbb{K}^{d' \times d} \) and \( \overline{a} \in \mathbb{K}^{d'} \) such that for any \( \overline{v} \in \mathbb{K}^d \), \( f(\overline{v}) = M.\overline{v} + \overline{a} \), it is linear if \( \overline{a} = \overline{0} \). We note such a function \((M, \overline{a})\) and abusively write \( f = (M, \overline{a}) \). We
Lemma 4.3. Every another PA by Karianto [15]:

\[ (\ministic A, \phi) \text{ with } (f \circ g)(x) = g(f(x)). \]

Definition 4.1 (affine Parikh automaton). A \( \mathbb{K} \)-affine Parikh automaton \((\mathbb{K} \text{-APA})\) of dimension \(d\) is a triple \((A, U, C)\) where \(A = (Q, \Sigma, \delta, q_0, F)\), \(U\) is a morphism from \(\delta^* \to \mathcal{F}_d^\mathbb{K}\) and \(C \subseteq \mathbb{K}^d\) is a \(\mathbb{K}\)-definable set; recall that \(U\) need only be defined on \(\delta\), and that, in particular, \(U(\varepsilon)\) is the identity function.

To simplify the notations, we write \(U_\pi\) for \(U(\pi)\). The language of the APA is \(L(A, U, C) = \{ \mu(\pi) \mid \pi \in \text{Run}(A) \land U_\pi(\emptyset) \in C \}\). The \(\mathbb{K}\)-APA is said to be deterministic \((\mathbb{K} \text{-DetAPA})\) if \(A\) is. We write \(\mathcal{L}_{\mathbb{K} \text{-APA}}\) (resp. \(\mathcal{L}_{\mathbb{K} \text{-DetAPA}}\)) for the class of languages recognized by \(\mathbb{K}\)-APA (resp. \(\mathbb{K}\)-DetAPA).

Remark 4.2. It is easily seen that \(N\)-APA (resp. \(N\)-DetAPA) are a generalization of CA (resp. DetCA). Indeed, let \((A, C)\) be a CA and define, for \(t \in \delta\), \(U_t = (Id, \Phi(t))\) where \(Id\) is the identity matrix of dimension \(|\delta| \times |\delta|\). Then \(L(A, C) = L(A, U, C)\). We will later see that this containment is strict.

We present a normal form for APA that is similar to a normal form given for PA by Karianto [15]:

Lemma 4.3. Every \(\mathbb{K}\)-APA \((A, U, C)\) of dimension \(d\) has the same language as another \(\mathbb{K}\)-APA \((A', U', C')\) of dimension \(d + 1\) with the three following properties:

(i) the initial state of \(A'\) has no incoming transition;
(ii) the automaton \(A'\) is complete;
(iii) every state of \(A'\) is final.

The same holds for \(\mathbb{K}\)-DetAPA.

Proof. Let \((A, U, C)\) be a \(\mathbb{K}\)-APA of dimension \(d\) where \(A = (Q, \Sigma, \delta, q_0, F)\), \(U : \delta^* \to \mathcal{F}_d^\mathbb{K}\), and \(C \subseteq \mathbb{K}^d\). We ensure incrementally the three properties; that is, we assume for each property that the previous ones hold.

Ensuring (i). We define \((A', U', C')\) as follows: \(A' = (Q', \Sigma', \delta', q_0', F')\), where \(Q' = Q \cup \{q_\text{fresh}\}\), with \(q_\text{fresh}\) a fresh state; \(\Sigma' = \Sigma\); \(\delta' = \delta \cup \delta_\text{fresh}\) with \(\delta_\text{fresh} = \{(q_\text{fresh}, a, q) \mid (q_0, a, q) \in \delta\}; q_0' = q_\text{fresh}\); if \(q_0 \in F\), then \(F' = F \cup \{q_\text{fresh}\}\) and otherwise \(F' = F\). Note that \(A'\) is deterministic if \(A\) is, and that \(L(A) = L(A')\). We define \(U' : \delta' \to \mathcal{F}_d^\mathbb{K}\) as follows. For \((q_\text{fresh}, a, q) \in \delta_\text{fresh}\), \(U'_{(q_\text{fresh}, a, q)} = U_{(q_0, a, q)}\) and for \(t \in \delta\), we have \(U'_t = U_t\). Finally, we let \(C' = C\). Then \(L(A, U, C) = L(A', U', C')\) and \((A', U', C')\) verifies (i).

Ensuring (ii). Now suppose \((A, U, C)\) verifies (i). Let \(A'\) be the automaton \(A\) in which an additional nonfinal sink state \(q_\text{sink}\) is added – that is, if a state \(q \in Q\) has no outgoing transition labeled \(a \in \Sigma\), the transition \((q, a, q_\text{sink})\) is added to \(A'\), and \(q_\text{sink}\) has \(|\Sigma|\) self-loops, labeled by each letter of \(\Sigma\). The new transitions of \(A'\) are associated with some function (for instance, the identity or the zero
function); the constraint set $C$ is left unchanged. This leaves both the language and the determinism the APA unchanged, and $A'$ now verifies (i) and (ii).

Ensuring (iii). Now suppose $(A, U, C)$ verifies (i) and (ii). We define $A'$ as $(Q, \Sigma, \delta, q_0, Q)$, i.e., the automaton $A$ with all states final. Let us define the $\mathbb{K}$-APA $(A', U', C')$ of dimension $d + 1$ where we fix $U': \delta \rightarrow \mathcal{F}_{d+1}^\mathbb{K}$ such that the last component of the affine functions serves as a flag: it is set to 1 if the last state reached is in $F$, and 2 otherwise – this component takes the value 0 only for the empty path. Formally, for $t \in \delta, \overline{x} \in \mathbb{K}^d$, and $f \in \mathbb{K}$:

$$U_t'(\overline{x}, f) = \begin{cases} U_t(\overline{x}), & 1 \text{ if } \text{To}(t) \in F, \\ 2 & \text{otherwise} \end{cases}.$$ 

Let us remark that the ability of APA to use constant functions (and not only translations, as in PA) allows to simplify the construction given by Karianto [15]. Finally, if $\varepsilon \in L(A, U, C)$, we let $C' = C \times \{1\} \cup \{0^{d+1}\}$, and otherwise, we let $C' = C \times \{1\}$. We argue that $L(A, U, C) = L(A', U', C')$. For the empty word, the construction is such that $\varepsilon \in L(A, U, C) \rightarrow \varepsilon \in L(A', U', C')$. Now if $\varepsilon \notin L(A, U, C)$ then $U'_\varepsilon(\overline{0}) = \overline{0} \notin C'$, thus $\varepsilon \notin L(A', U', C')$. Now let $w$ be a nonempty word in $L(A, U, C)$ and let $\pi$ be an accepting path in $A$ such that $\mu(\pi) = w$ and $U_\pi(\overline{0}) \in C$. Then $\pi$ is also an accepting path in $A'$, and as $\text{To}(\pi) \in F$, we have that $U'_\pi(\overline{0}) = (U_\pi(0^d), 1)$, and as $U_\pi(\overline{0}) \in C$, we have that $U'_\pi(\overline{0}) \in C \times \{1\}$. Hence $\mu(\pi) = w$ is in $L(A', U', C')$. Conversely, suppose $w$ is a nonempty word in $L(A', U', C')$ and let $\pi$ be an accepting path in $A'$ such that $\mu(\pi) = w$ and $U'_\pi(\overline{0}) \in C'$. Then $\pi$ is a path in $A$, and as $U'_\pi(\overline{0}) = (U_\pi(0^d), 1)$, we have that $\text{To}(\pi) \in F$ and $U_\pi(\overline{0}) \in C$, thus $\mu(\pi) = w$ is in $L(A, U, C)$.

We may verify that $(A', U', C')$ satisfies the three properties and that the language $L(A', U', C')$ is equal to the language $L(A, U, C)$. Moreover, $A'$ is deterministic if $A$ is.

\[\square\]

4.1. Affine Parikh automata on $\mathbb{Q}$ and $\mathbb{N}$

In this section, we show that the expressive power of affine Parikh automata is independent from the choice of $\mathbb{K}$. We first show that the constraint set can have a similar form in the two cases. We call basic formula a quantifier-free formula which uses the function symbols + for addition and $\lambda_n$, $n \in \mathbb{N}$, for scalar multiplication, together with the relation symbol $<$ and constants from $\mathbb{N}$ – equality is expressible, as $t_1 = t_2$ is equivalent to $\neg(t_1 < t_2) \land \neg(t_2 < t_1)$. Of course, the scalar multiplication $\lambda_n(t)$ can be replaced by $t + \ldots + t$ where $t$ appears $n$ times, but its inclusion simplifies the proofs slightly. We remark, for future reference, the following property of basic formulas. For $\overline{v}$ a vector of natural numbers and $\phi$ a basic formula, the fact that $\phi$ is true of $\overline{v}$ is independent of the underlying model, whether it is $\mathbb{Q}$ or $\mathbb{N}$. In symbols, $\mathbb{Q} \models \phi(\overline{v})$ iff $\mathbb{N} \models \phi(\overline{v})$. 
The following lemma shows in particular that the constraint set of $\mathbb{Q}$-APA can be expressed as a basic formula:

**Lemma 4.4.** Every $\mathbb{Q}$-definable set can be expressed as a basic formula.

*Proof.* Recall that a $\mathbb{Q}$-definable set can be expressed with a quantifier-free formula $\phi$. Thus, we need only get rid of the $c$’s not in $\mathbb{N}$ appearing either as $\lambda_c$ or as a constant in $\phi$. First, note that we can suppose that if $\lambda_c(t)$ appears in $\phi$, with $t$ a term, then $t$ is some variable: we simply apply the distributivity of $\lambda_c$ (*i.e.*, replace $\lambda_c(t_1 + t_2)$ by $\lambda_c(t_1) + \lambda_c(t_2)$ and $\lambda_c(\lambda_c(t))$ by $\lambda_{c \times c'}(t)$), then replace $\lambda_c(c')$ with $c'$ a constant by the constant $c \times c'$, neither of those operations changing the set defined. Second, we take care of the negative $c$’s. For any atomic formula $t_1 < t_2$ appearing in $\phi$, if the constant $c < 0$ appears in $t_1$, we remove it from $t_1$ and add $-c$ to $t_2$; if $c < 0$ appears as $\lambda_c(x)$ in $t_1$, with $x$ a variable, we remove it from $t_1$ and add $\lambda_{-c}(x)$ to $t_2$ (the same goes with $t_1$ and $t_2$ switched). Third and last, we take care of the denominators: let $N$ be the product of all the denominators appearing in the reduced fractions of the $c$’s appearing in $\phi$. Then any atomic formula $t_1 > t_2$ is replaced with the atomic formula $t'_1 > t'_2$ where any $c$ (appearing either as a constant or as $\lambda_c$) is replaced by $N \times c$: the fact that $c \geq 0$ implies that $(N \times c) \in \mathbb{N}$. Moreover, for any assignment, the value of $t'_1$ (resp. $t'_2$) is $N$ times the value of $t_1$ (resp. $t_2$), hence, the value of $t_1$ is greater than the value of $t_2$ iff the same holds for $t'_1$ and $t'_2$. \hfill $\square$

Over $\mathbb{N}$, the automaton is needed to incorporate some of the constraint set:

**Lemma 4.5.** Every $\mathbb{N}$-APA $(A, U, C)$ has the same language as another $\mathbb{N}$-APA $(A, U', C')$ where $C'$ can be expressed as a basic formula. The same holds for $\mathbb{N}$-DetAPA.

*Proof.* Recall that a semilinear set can be expressed as a basic formula with the additional relations $\equiv_p$, expressing congruence (*e.g.*, [6]). Thus we need only get rid of these relations. To do so, we equip the affine functions to compute their own value modulo $p$.

Let $(A, U, C)$ be an $\mathbb{N}$-APA (resp. $\mathbb{N}$-DetAPA) of dimension $d$ for which we suppose the initial state of $A$ has no incoming transition (Lem. 4.3), and let $\phi(x_1, \ldots, x_d)$ be the formula for $C$ of the form previously mentioned (*i.e.*, a basic formula with the additional relations $\equiv_p$). Suppose $\phi$ is not a basic formula, then there is a $p$ such that $\equiv_p$ appears in $\phi$. We define $(A, U', C')$ of the same language as $(A, U, C)$ with $C'$ expressed by $\phi$ in which the $\equiv_p$ relation, for this specific $p$, is replaced by some basic formulas. Applying this process repeatedly gives an $\mathbb{N}$-APA (resp. $\mathbb{N}$-DetAPA) of the same language with its constraint set expressible as a basic formula.

Our goal is to modify $U$ so that for each $\overline{v} \in \{0, \ldots, p-1\}^d$, there is an additional variable $m_{\overline{v}}$ available to $\phi$ which is set to 1 iff the value of $x_i$ modulo $p$ is $v_i$, for all $1 \leq i \leq d$ (thus only one of the $m_{\overline{v}}$’s can be set to 1). With this information
available, all the atomic formulas of the form $t_1 \equiv_p t_2$, for this specific $p$, can be rewritten without $\equiv_p$ using a basic formula:

$$t_1 \equiv_p t_2 \leadsto \bigvee_{\overline{v} \in \{0, \ldots, p-1\}^d} (m_{\overline{v}} = 1).$$

Let $t$ be a transition of $A$; we give $U'_t \in \mathcal{F}_d^{p}$. In order to do this, we define an additional 0-1-matrix $M_t$ of dimension $p^d \times p^d$, which we index by vectors in $\{0, \ldots, p-1\}^d$ in some natural way (in particular, $0^d$ is the index of the first row). We let $M_t[\overline{v}, \overline{v}] = 1$ iff $\overline{v} = U_t(\overline{v}) \mod p$, where the modulo is taken component-wise.

We are now ready to define $U'_t(\overline{x}, \overline{m})$, for $\overline{x} \in \mathbb{N}^d$ and $\overline{m} \in \mathbb{N}^p$. If $t$ is an outgoing transition of the initial state of $A$, then $U'_t(\overline{x}, \overline{m}) = (U_t(\overline{x}), M_t(1,0))$, where $(1,0)$ is the column vector $(1,0,\ldots,0) \in \mathbb{N}^p$. Otherwise, we let $U'_t(\overline{x}, \overline{m}) = (U_t(\overline{x}), M_t(\overline{m}))$. Note that in both definitions, $U'_t$ is indeed an affine function. Now with $\overline{m_1}$ (resp. $\overline{m_2}$) the vector in $\{0,1\}^p$ having a 1 only in position $\overline{x} \mod p$ (resp. $U_t(\overline{x}) \mod p$), we have $U'_t(\overline{x}, \overline{m_1}) = (U_t(\overline{x}), \overline{m_2})$. Moreover, the initial value of $\overline{x}$ being $0^d$, those hypotheses are established at the first transition taken. Thus for a nonempty path $\pi$, and with $\overline{m}$ the vector in $\{0,1\}^p$ having a 1 only in position $U_\pi(0^d) \mod p$, we have: $U'_\pi(0) = (U_\pi(0^d), \overline{m})$.

As previously discussed, $\phi$ can now be rewritten as $\phi'$ without the use of $\equiv_p$: $\phi'$ has access to the usual variables $x_1,\ldots,x_d$ and to variables $m_{\overline{v}}$ for $\overline{v} \in \{0,\ldots,p-1\}^d$. We take care of the empty word by letting $\phi'$ consider $m_{\overline{v}}$ to be 1 if no other $m_{\overline{v}}$ variable is set. Thus, with $C'$ the set defined by $\phi'$, we have that $L(A,U,C) = L(A,U',C')$ and $\phi'$ has one less $p$ appearing as $\equiv_p$ than $\phi$. □

Before proving the main result of this section, we show that affine functions, in their full generality, are not needed within $\mathbb{K}$-APA or $\mathbb{K}$-DetAPA:

**Lemma 4.6.** The language of any $\mathbb{K}$-APA is also the language of a $\mathbb{K}$-APA in which every affine function is either constant or linear – for both $\mathbb{K} = \mathbb{Q}$ and $\mathbb{K} = \mathbb{N}$. Moreover, the first transition of a run is always associated with a constant function. The same holds for $\mathbb{K}$-DetAPA.

**Proof.** Let $(A,U,C)$ be a $\mathbb{K}$-APA (resp. $\mathbb{K}$-DetAPA) of dimension $d$ and suppose, thanks to Lemma 4.3, that the initial state of $A$ has no incoming transition. We define a $\mathbb{K}$-APA (resp. $\mathbb{K}$-DetAPA) $(A',U',C')$ where the outgoing transitions of the initial state of $A$ initialize the registers with the values of all the constant parts given by $U$. Specifically, we define the morphism $U': \delta' \to \mathcal{F}_d^{\mathbb{K}}$ as follows. Identify the transition set of $A$ with $\{t_1,\ldots,t_n\}$, write $U_{t_i} = (M_{t_i}, \overline{v}_{t_i})$, for $i \in \{1,\ldots,n\}$, and define $\hat{v} = (\overline{v_1},\ldots,\overline{v_n}) \in \mathbb{K}^n$. Then for $t$ an outgoing transition of the initial state, $U'_t$ is the constant function with value $(U_t(0^d), \hat{v})$; for the other
For $t_i$'s, we set $U'_t(x, y_1, \ldots, y_n) = (M_i x + y_i, y_1, \ldots, y_n)$, and in this case, $U'_t$ is the linear function $(M'_i, 0)$ where here and in the following $0$ is of dimension $d + dn$ and:

\[
M'_i = \begin{pmatrix}
M_i & 0_d & \cdots & 0_d & Id_d & 0_d & \cdots & 0_d \\
0_d & \ddots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\vdots & \ddots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\vdots & \ddots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0_d & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{pmatrix}
\]

with $0_k$ (resp. $Id_k$) the zero (resp. identity) matrix of dimension $k \times k$. Finally, we let $C' = C \times \mathbb{K}^{dn}$.

We now show that $L(A, U, C) = L(A, U', C')$. First, $\varepsilon \in L(A, U, C)$ iff $\varepsilon \in L(A)$ and $U_\varepsilon(\emptyset) = \emptyset \in C$, the latter being equivalent to $U'_\varepsilon(\emptyset) = \emptyset \in C'$, thus $\varepsilon \in L(A, U, C)$ iff $\varepsilon \in L(A, U', C')$. Now let $\pi$ be a path in $A$ starting from the initial state. Suppose $|\pi| = 1$ then $U'_\pi(\emptyset) = (U_\pi(0^d), \hat{v})$. For $|\pi| > 1$, let $\pi = pt$, then:

\[
U'_\pi(\emptyset) = U'_t(U'_p(\emptyset)) = U'_t(U'_p(0^d), \hat{v}) = (U_\pi(0^d), \hat{v}).
\]

Thus let $w$ be a nonempty word in $L(A, U, C)$ and let $\pi$ be an accepting path in $A$ labeled $w$ and such that $U_\pi(\emptyset) \in C$. Then $U'_\pi(\emptyset) = (U_\pi(0^d), \ldots)$ which is in $C \times \mathbb{K}^{dn} = C'$, thus $w \in L(A, U', C')$. Conversely, let $w$ be a nonempty word in $L(A, U', C')$ and let $\pi$ be an accepting path in $A$ labeled $w$ such that $U'_\pi(\emptyset) \in C'$. We have that $U'_\pi(\emptyset) = (U_\pi(0^d), \ldots)$ is in $C' = C \times \mathbb{K}^{dn}$, thus $U_\pi(0^d) \in C$ and $w \in L(A, U, C)$.

We are now ready to show that the choice of $\mathbb{K}$ in APA does not influence the class of languages defined:

**Theorem 4.7.** $L_{Q-DetAPA} = L_{N-DetAPA}$ and $L_{Q-APA} = L_{N-APA}$. Moreover, these correspondences are effective and do not change the underlying automaton.

**Proof.** ($L_{Q-APA} \subseteq L_{N-APA}$ and $L_{Q-DetAPA} \subseteq L_{N-DetAPA}$). Let $(A, U, C)$ be a $Q$-APA (resp. $Q$-DetAPA) of dimension $d$, with $\delta$ the set of transitions of $A$. The underlying automaton $A$ will remain the same throughout the proof.
We suppose that the empty word is not in $L(A)$ it is a simple task to add it back at the very end of this construction if needed. Thanks to Lemma 4.6, we assume that all the functions given by $U$ are either linear or constant. Lemma 4.4 then asserts that $C$ is expressible as a basic formula $\phi$. We first ensure that no constant appears in $\phi$ by replacing each of them by a variable (e.g., if $\lambda_3(x)+8$ is a term in $\phi$, we replace it by $\lambda_3(x)+y$ where $y$ is a new variable). Let $\phi'$ be this modified formula and, for $c_1 < c_2 < \ldots < c_p \in \mathbb{K}$ he increasing sequence of the $p$ constants that appear in $\phi$, let $y_1, y_2, \ldots, y_p$ be the associated sequence of new variables. We now update $U$ so that it gives the value $c_i$ to $y_i$, for all $i$. Let $\overline{c} = (c_1, c_2, \ldots, c_p)$ and define $U'$ from $U$ as follows. For $t$ such that $U_t$ is constant, set $U'_t(\overline{x}, \overline{c}) = (U_t(0^d), \overline{c})$, which is still a constant function; and for $t$ such that $U_t$ is linear, set $U'_t(\overline{x}, \overline{c}) = (U_t(\overline{x}), \overline{c})$, which is also still linear. We let $C'$ be the set described by $\phi'$; it verifies $\{\overline{c} \mid (\overline{x}, \overline{c}) \in C'\} = C$. As the first transition of any run in $A$ is associated, by $U$, with a constant function, any nonempty run $\pi$ in $A$ verifies $U'_{\pi}(\overline{c}) = (U_{\pi}(0^d), \overline{c})$. Thus the variables $y_1, \ldots, y_p$ of $\phi'$ are indeed set to $c_1, \ldots, c_p$, implying that $L(A, U, C) = L(A, U', C')$. From now on we denote $d + p$ by $n$.

We now change $U'$ so that the constants and matrices appearing in the $U'_i$’s are all integer-valued. Let $N$ be the product of all the denominators appearing in the reduced fractions of the entries of the matrices and vectors given by $U'$. By defining $U''_i = N \times U'_i$, we thus ensure that all the values appearing in the definition of $U'_i$ are integers, hence $U''$ is a function from $\delta^*$ to $\mathbb{F}^n_{\mathbb{Z}}$. Moreover, as all the functions are either linear or constant, this implies that for any path $\pi$, there is a $k \leq |\pi|$ such that $U''_{\pi} = N^k \times U'_{\pi}$. But as all the atomic formulas of $\phi'$ are of the form $t_1 < t_2$ where no constant appears and all the $\lambda_c$ have $c > 0$, we have that $\phi'(\overline{c})$ is true iff $\phi'(K \times \overline{c})$ is true. Thus $L(A, U, C) = L(A, U'', C')$.

Finally, we change $U''$ and $C'$ so that they are $\mathbb{N}$-valued. We define $U'''$ as $U''$ where the positive and negative computations are made in different components. Consider $U''_i$ as $n$ affine functions from $\mathbb{Q}^n$ to $\mathbb{Q}$: $U''_i(\overline{x}) = (f_1(\overline{x}), \ldots, f_n(\overline{x}))$. Then let $1 \leq i \leq n$, and write $f_i(\overline{x}) = c + \sum_{j=1}^n v_j \times x_j$.

Let us write $J^+ = \{1 \leq j \leq n \mid v_j \geq 0\}$ and $J^- = \{1 \leq j \leq n \mid v_j < 0\}$. Now, we define $f^+_i$ and $f^-_i$ by:

$$f^+_i(\overline{x}^+, \overline{x}^-) = \max(c, 0) + \sum_{j \in J^+} |v_j| \times x_j^+, \text{and,}$$

$$f^-_i(\overline{x}^+, \overline{x}^-) = |\min(c, 0)| + \sum_{j \in J^-} |v_j| \times x_j^-.$$

Now define $U'''_i : \mathbb{N}^{2n} \rightarrow \mathbb{N}^{2n}$ as $U'''_i(\overline{x}^+, \overline{x}^-) = (f^+_1, f^-_1, \ldots, f^+_n, f^-_n)(\overline{x}^+, \overline{x}^-)$, where $\overline{x}^+, \overline{x}^- \in \mathbb{N}^n$. The main property of this construction is that for a path $\pi$, we have:

$$U'''_{\pi}(\overline{0}) = (a^+_1, a^-_1, \ldots, a^+_n, a^-_n) \implies U''_{\pi}(\overline{0}) = (a^+_1 - a^-_1, \ldots, a^+_n - a^-_n).$$
Thus define $C''$ as:

$$C'' = \{(a_1^+, a_1^-, \ldots, a_n^+, a_n^-) \mid (a_1^+, a_1^-, \ldots, a_n^+, a_n^-) \in C'\}.$$ 

Now $C''$ is a $Q$-definable set because $C'$ is $Q$-definable, thus $C''$ is expressible as a basic formula. But basic formulas on natural numbers take their truth values regardless of whether $K = N$ or $K = Q$, thus $C'' \cap N^{2n}$ is $N$-definable.

Finally, $(A, U'', C'', N^{2n})$ is an N-APA (resp. $N$-DetAPA) of the same language as $(A, U, C)$.

$(L_{N-APA} \subseteq L_{Q-APA}$ and $L_{N-DetAPA} \subseteq L_{Q-DetAPA}$). This is a consequence of Lemma 4.5. Let $(A, U, C)$ be an N-APA (resp. $N$-DetAPA). Now, by Lemma 4.5, let $(A, U', C')$ be an N-APA (resp. $N$-DetAPA) with the same language and with $C'$ expressible as a basic formula. The fact that basic formulas take their truth value on natural numbers regardless of the underlying model implies that there exists a $Q$-definable set $C''$ such that $C'' \cap N^d = C'$ – this is the set described by the basic formula for $C'$ interpreted in $Q$ – and thus $(A, U', C'')$ is a $Q$-APA (resp. $Q$-DetAPA) of the same language as $(A, U, C)$.

The previous result allows us to write $L_{DetAPA}$ for $L_{Q-DetAPA} = L_{N-DetAPA}$ and $L_{APA}$ for $L_{Q-APA} = L_{N-APA}$.

4.2. Closure properties of $L_{APA}$ and $L_{DetAPA}$

The pointed concatenation of $L$ and $L'$ is any language of the form $L \cdot \{\#\} \cdot L'$ where # does not appear in a word of $L$. The arguments used by Klaedtke and Rueß [16] apply equally well to $K$-APA and $K$-DetAPA, showing:

**Proposition 4.8.** (1) $L_{APA}$ is closed under union, intersection, concatenation, nonerasing morphisms, and inverse morphisms; (2) $L_{DetAPA}$ is closed under union, intersection, inverse morphisms, complement, and pointed concatenation.

**Proof.** (Union and intersection). Let $(A', U', C')$ and $(A'', U'', C'')$ be two $K$-APA (resp. $K$-DetAPA) of dimension $d'$ and $d''$, respectively, and suppose that $A'$ and $A''$ are complete and with every state final (Lem. 4.3). We suppose moreover, w.l.o.g., that the alphabets of the automata are the same. Let $L' = L(A', U', C')$ and $L'' = L(A'', U'', C'')$. We construct two $K$-APA (resp. $K$-DetAPA) $(A, U, C^d)$ and $(A, U, C^{d''})$ such that their languages are the union and intersection, respectively, of $L'$ and $L''$. Let $A' = (Q', \Sigma', \delta', q_0', Q')$ and $A'' = (Q'', \Sigma'', \delta'', q_0'', Q'')$, and define the Cartesian product of $A'$ and $A''$ by $A = (Q' \times Q'', \Sigma', \delta, (q_0', q_0''), Q' \times Q'')$ with:

$$\delta = \{((p', p''), a, (q', q'')) \mid (p', a, q', q'') \in \delta' \land (p'', a, q'', q'') \in \delta''\}.$$ 

This automaton is deterministic if both $A'$ and $A''$ are. Define $h'$ (resp. $h''$), to be the morphism from $\delta^*$ to $(\delta')^*$ (resp. to $(\delta'')^*$) such that $h'((p', p''), a, (q', q'')) = (p', a, q')$ (resp. $h''((p', p''), a, (q', q'')) = (p'', a, q'')$); the fact that $A'$ and $A''$ are complete implies that for any run $\pi'$ in $A'$ and $\pi''$ in $A''$ with the same label, there is a run $\pi$ in $A$ such that $h'(\pi') = \pi'$ and $h''(\pi'') = \pi''$. Then we let $U : \delta^* \rightarrow F_{d+d''}^\infty$. 

compute the values of $U'$ in the first $d'$ components and the values of $U''$ in the last $d''$ components, that is, for $\overline{x'}, \overline{x''} \in \mathbb{K}^{d'}, \mathbb{K}^{d''}$, and $t \in \delta$:

$$U_t(\overline{x'}, \overline{x''}) = (U'_{h'_t(\overline{x'})}(\overline{x'}), U''_{h''_t(\overline{x''})}(\overline{x''})).$$

Finally, we let $C'^{\cup} = C' \times \mathbb{K}^{d''} \cup \mathbb{K}^{d'} \times C''$ and $C'^{\cap} = C' \times C''$. We argue that $L(A, U, C') = L' \cup L''$ and $L(A, U, C') = L' \cap L''$.

Let $\pi$ be a run in $A$. Then $h'(\pi)$ is a run in $A'$, $h''(\pi)$ is a run in $A''$, and both have the same label as $\pi$. Moreover, $U_\pi(\overline{0}) = (U'_{h'_t(\overline{0})}(0^{d'}), U''_{h''_t(\overline{0})}(0^{d''}))$. Thus if $U_\pi(\overline{0}) \in C'^{\cup}$ then $\mu_A(\pi) \in L(A, U, C'^{\cup})$, and $U'_{h'_t(\overline{0})}(0^{d'}) \in C'$ or $U''_{h''_t(\overline{0})}(0^{d''}) \in C''$, thus $\mu_A(\pi) \in L' \cup L''$. Likewise, if $U_\pi(\overline{0}) \in C'^{\cap}$ then $\mu_A(\pi) \in L(A, U, C'^{\cap})$, and both $U'_{h'_t(\overline{0})}(0^{d'}) \in C'$ and $U''_{h''_t(\overline{0})}(0^{d''}) \in C''$ thus $\mu_A(\pi) \in L' \cap L''$.

For the converse, let $w \in L'$ and let $\pi'$ be a run in $A'$ such that $\mu_A'(\pi') = w$ and $(U'(\pi'))(\overline{0}) \in C'$. Then there is a run $\pi$ in $A$ such that $h'(\pi) = \pi'$. Moreover, $U_\pi(\overline{0}) = ((U'_{h'_t(\overline{0})}(0^{d'}), (U''_{h''_t(\overline{0})}(0^{d''})))$ which is in $C' \times \mathbb{K}^{d''}$, thus in $C'^{\cup}$, and thus $w \in L(A, U, C'^{\cup})$. Likewise, if $w \in L' \cap L''$, and let $\pi''$ (resp. $\pi'''$) be a run in $A''$ (resp. $A'''$) such that $\mu_A''(\pi'') = w$ and $U'_{h'_t(\overline{0})}(0^{d'}) \in C'$ (resp. $\mu_A'''(\pi''') = w$ and $U''_{h''_t(\overline{0})}(0^{d''}) \in C''$). There exists a path $\pi$ in $A$ such that $h'(\pi) = \pi'$ and $h''(\pi) = \pi''$, and it is such that $U_\pi(\overline{0}) = (U'_{h'_t(\overline{0})}(\overline{0}), U''_{h''_t(\overline{0})}(\overline{0}))$ which is in $C' \times C''$, that is, $C'^{\cap}$, thus $w \in L(A, U, C'^{\cap})$.

(Inverse morphisms). We first tackle the $\mathbb{K}$-DetAPA case, which is based on the classical construction on finite automata and followed by the addition of the affine functions. Let $(A, U, C)$ be a $\mathbb{K}$-DetAPA over the alphabet $\Sigma$, and let $h: \Sigma^* \to \Sigma^*$ be a morphism; we will give a $\mathbb{K}$-DetAPA $(A', U', C)$ for the language $h^{-1}(L(A, U, C'))$. We first construct $A'$ such that its language is $h^{-1}(L(A))$. Let $A = (Q, \Sigma, \delta, q_0, F)$, and write $\text{Path}(q, u, q')$ for the only path in $A$ from $q$ to $q'$ labeled $u$ if it exists, $\bot$ otherwise. Further, we let $\text{Path}(q, \varepsilon, q) = \varepsilon$, i.e., we consider that the empty path is going and ending in any given state. Then $A' = (Q, \Sigma', \delta', q_0, F)$ where:

$$\delta' = \{(q, a, q') \in Q \times \Sigma' \times Q \mid \text{Path}(q, h(a), q') \neq \bot\}.$$

The automaton $A'$ is such that $L(A') = h^{-1}(L(A))$ and is deterministic. In particular, if $h(a) = \varepsilon$, then a loop labeled $a$ appears on each state.

When a word $w$ is read in $A'$ from some state $q$ to a state $q'$, the equivalent action in $A$ is to take the path $\text{Path}(q, h(w), q')$; thus we let $U'_{(q, a, q')} = U_{\text{Path}(q, h(a), q')}$, and in particular, if a transition is labeled with a letter $a$ such that $h(a) = \varepsilon$, then the associated function is the identity. Then for $\pi'$ a path in $A'$ and $\pi$ its counterpart in $A$ (that is, $\pi = \text{Path}(\text{From}(\pi'), h(\mu(\pi'))), T(\pi'))$, we have that $U'_{\pi'} = U_\pi$. Now let $w \in L(A')$, $\pi'$ be the accepting path with label $w$ in $A'$, and $\pi$ be the accepting path with label $h(w)$ in $A$. Then $U_{\pi'}(\overline{0}) = U_\pi(\overline{0})$. Thus we have that $h(w) \in L(A, U, C)$ iff $h(w) \in L(A)$ and the path $\pi$ for $h(w)$ in $A$ is such that $U_\pi(\overline{0}) \in C$, which is the case if $w \in L(A')$ and the path $\pi'$ for $w$ in $A'$ is such that $U'_{\pi'}(\overline{0}) \in C$, that is if $w \in L(A', U', C)$, concluding this case.
We now focus on the nondeterministic case. Let \((A, U, C)\) be a \(\mathbb{K}\)-APA over the alphabet \(\Sigma\) and let \(h: \Sigma^* \rightarrow \Sigma^*\) be a morphism. Here, for some states \(q, q'\) of \(A\), we may have several paths from \(q\) to \(q'\) with the same label – say we have \(k\) paths. To circumvent this problem, we use at least \(k\) copies of the \(A'\) of the deterministic case: we go from the \(i\)-th copy of \(q\) to the \(j\)-th of \(q'\) applying the affine functions corresponding to the \(j\)-th of the \(k\) paths.

Formally, let \(A = (Q, \Sigma, \delta, q_0, F)\). Define \(\text{Paths}(q, u, q')\) as the set of paths in \(A\) from \(q\) to \(q'\) labeled \(u\), and impose an order on this set (say, lexicographical order). Again, we consider the empty path as going and ending in any given state, thus we let \(\text{Paths}(q, \varepsilon, q) = \{\varepsilon\}\). Let \(M\) be the maximum number of elements in \(\text{Paths}(q, h(a), q')\) for \(q, q' \in Q\), and \(a \in \Sigma'\). We define an \(A'\) similar to the deterministic case, but duplicated \(M\) times to obtain the \(\mathbb{K}\)-APA \((A', U', C)\) for \(h^{-1}(L(A, U, C))\). For \(1 \leq i \leq M\) and for a state \(q\) in \(A'\), we write \(q_i\) for a fresh copy of \(q\) indexed by \(i\) (when \(q = q_0\) we write \((q_0)_i\) as \(q_{0,i}\)); we use this notation to define an automaton \(A'\) that includes \(M\) copies of the deterministic case one.

Let \(A' = (Q', \Sigma', \delta', q_0, 1, F')\) where:

- \(Q' = \{q_i \mid q \in Q, 1 \leq i \leq M\}\);
- \(\delta' = \{(q_i, a, q_j^i) \in Q' \times \Sigma' \times Q' \mid 1 \leq i, j \leq |\text{Paths}(q, h(a), q')|\}\);
- \(F' = \{q_i \mid q \in F, 1 \leq i \leq M\}\).

Again we have that \(L(A') = h^{-1}(L(A))\). Finally, define \(U'\) by:

\[ U'_{(q, a, q')} = U \pi \]  

where \(\pi\) is the \(j\)-th path in \(\text{Paths}(q, h(a), q')\).

The deterministic case corresponds to \(M = 1\), and in this case, the constructed \(\mathbb{K}\)-APA is the same as in the previous construction. Now suppose \(\text{Paths}(q, h(a), q')\) has more than two elements for some \(q, q' \in Q\) and \(a \in \Sigma'\). In particular, the two transitions \((q_1, a, q'_1)\) and \((q_1, a, q'_2)\) are in \(A'\); the affine functions associated are such that taking the first (resp. second) transition applies the same function as going through the first (resp. second) path of \(\text{Paths}(q, h(a), q')\) in \(A'\). Thus, once again, the possible values computed by the affine functions while reading some \(h(w)\) in \(A\) are the same as those computed while reading \(w\) in \(A'\). By the same token as in the deterministic case, \(L(A', U', C) = h^{-1}(L(A, U, C))\).

(Concatenation). Let \((A', U', C')\) and \((A'', U'', C'')\) be two \(\mathbb{K}\)-APA of dimension \(d'\) and \(d''\), respectively, and write \(L' = L(A', U', C')\) and \(L'' = L(A'', U'', C'')\). We construct a \(\mathbb{K}\)-DetAPA \((A, U, C)\) of dimension \(d' + d''\) for \(L = L' \cdot L''\). Here, \(A\) is the merging of \(A'\) and \(A''\), where for all transitions in \(A''\) from the initial state to some state \(q\), a transition from each final state of \(A'\) to \(q\) with the same label is added. We then compute \(U'\) and \(U''\) in parallel.

Formally, let \(A' = (Q', \Sigma', \delta', q_0', F')\) and \(A'' = (Q'', \Sigma'', \delta'', q_0'', F'')\), and suppose \(Q' \cap Q'' = \emptyset\). We assume that \(\varepsilon \notin L(A'')\); otherwise, if \(\varepsilon \in L'',\) then \(L = L' \cdot (L'' \setminus \{\varepsilon\}) \cup L'\), and the closure under union allows us to conclude. Define \(A\) as the
deterministic automaton $(Q, \Sigma, \delta, q_0, F)$ where:

- $Q = Q' \cup Q''$, $\Sigma = \Sigma' \cup \Sigma''$;
- $\delta = \delta' \cup \delta'' \cup \{(p, a, q) \mid p \in F' \land (q_0'', a, q) \in \delta''\}$;
- $q_0 = q_0'$ and $F = F''$.

The language of $A$ is thus $L(A') : L(A'')$. We define $U : \delta^* \rightarrow \mathbb{K}^{d'+d''}$ so that the $d'$ first components are used for the computations of $A'$, and the $d''$ last for the computations of $A''$, i.e., for $\pi \in \mathbb{K}^{d'}$ and $\eta \in \mathbb{K}^{d''}$, we let $U_t(\pi, \eta) = (U_t'(\pi), \eta)$ if $t \in \delta'$, $(\pi, U_t''(\eta))$ if $t \in \delta''$, and $(U(q_0''(a, q), \eta))$ if $t = (p, a, q) \notin \delta' \cup \delta''$. Finally, we let $C$ to be the $\mathbb{K}$-definable set $C' \times C''$.

Let $\pi \in \text{Run}(A)$, then $\pi$ can be written as $\pi'(p, a, q)\pi''$ where $\pi' \in \text{Run}(A')$ and $(q_0'', a, q)\pi'' \in \text{Run}(A'')$. Conversely, for two paths $\pi' \in \text{Run}(A')$, $(q_0'', a, q)\pi'' \in \text{Run}(A'')$, the path $\pi'(\text{To}(\pi'), a, q)\pi''$ is a run in $A$. Moreover, in both cases, it holds that:

$$U_\pi(\overline{0}) = (U_{\pi'}'(0^{d'}), U_{\pi''}''(0^{d''})).$$

Thus $L = L(A, U, C)$.

(Nonerasing morphisms). Let $(A, U, C)$ be a $\mathbb{K}$-APA over the alphabet $\Sigma$ and $h : \Sigma^* \rightarrow \Sigma^*$ be a nonerasing morphism, that is, for all $a \in \Sigma, h(a) \neq \varepsilon$. We construct a $\mathbb{K}$-APA for $h(L(A, U, C))$ where the main task is the following. For a letter $a \in \Sigma$ and $w = w_1 \ldots w_n = h(a)$, a transition $t = (q, a, q')$ of $A$ is replaced by $n$ transitions $(q, w_1, q_{t,1}), \ldots, (q, t, n-1, w_n, q')$ where the $q_{t,i}$’s are fresh states named after the transition $t$. To make the proof concise, we rely on the closure under inverse morphism of $\mathbb{K}$-APA, previously shown. We give a $\mathbb{K}$-APA $(A', U', C')$ for the image of $h(L(A, U, C))$ under the morphism $g$ which maps $a \in \Sigma'$ to $a\#$, for $\# \notin \Sigma'$; we then have that $h(L(A, U, C)) = g^{-1}(L(A', U', C'))$, concluding the proof.

Formally, let $A = (Q, \Sigma, \delta, q_0, F)$ and for $t \in \delta$, write $q_{t,i}^+$ and $q_{t,i}^-$ to denote some fresh states. Let $\#$ be a symbol not in $\Sigma'$. Then $A' = (Q', \Sigma' \cup \{\#\}, \delta', q_0, F)$ where:

- $Q' = Q \cup \{q_{t,i}^+, q_{t,i}^- \mid t \in \delta \land 1 \leq i \leq |h(\mu(t))|\}$;
- $\delta' = \{(q, w_1, q_{t,1}^+), (q_{t,i}^-, \#, q_{t,i}^+), (q_{t,i}^+, w_{i+1}, q_{t,i+1}^+), (q_{t,i}^+, \#, q') \mid (q, a, q') \in \delta \land w_1 \ldots w_n = h(a) \land 1 \leq i < n\}$.

We now adjust $U'$ so that the computations of the two $\mathbb{K}$-APA are the same. We let $U'_t$ be the identity function for any $t$ with $\text{From}(t) \notin Q$, and for $t' = (q, a, q_{t,1}^-)$, we let $U'_{t'} = U_t$. We argue that this $\mathbb{K}$-APA recognizes $h(L(A, U, C))$ with a $\#$ in every even position. First, $L(A')$ is $h(L(A))$ in which a $\#$ is inserted in every even position. Next, let $w_1\# \ldots \# w_n\# \notin L(A')$ with $w_i \in \Sigma'$, and let $\pi'$ be a run with this label in $A'$ such that $U_{\pi'}'(\overline{0}) \in C$. Let $\pi$ be the corresponding path in $A$ defined by replacing each transition of the form $(q, a, q_{t,1}^+)$ by $t$ and removing the other transitions. Then $\pi$ is an accepting path, its label is in $h^{-1}(w_1 \ldots w_n)$, and $U_{\pi}(\overline{0}) = U_{\pi}'(\overline{0})$, thus $w_1 \ldots w_n \in h(L(A, U, C))$. Conversely, if $w \in L(A, U, C)$, then let $\pi$ be a run with label $w$ in $A$ such that $U_{\pi}(\overline{0}) \in C$. Then the path $\pi'$ in
Let \( L' \) whose only states of the form \( q_{i,1}^r \) are \( q_{i,1,1}, \ldots, q_{\pi,|w|,1}^r \) in that order is accepting and such that \( U'_\pi(\emptyset) = U_\pi(\emptyset) \) which is in \( C \). Thus its label, which is \( h(w) \) with \# inserted in every even position, is in \( L(A', U', C) \).

(Complement). Let \( (A, U, C) \) be a \( \mathbb{K} \)-DetAPA. A word is not in \( L(A, U, C) \) iff it is not in \( L(A) \) or, while being in \( L(A) \), the path \( \pi \) corresponding to the word is such that \( U_\pi(\emptyset) \notin C \). Thus the complement of \( L(A, U, C) \) is \( \overline{L(A)} \cup L(A, U, \overline{C}) \), which is in \( L_{\mathbb{K}} \)-DetAPA, semilinear sets being closed under complement.

(Pointed concatenation). This is similar to the closure under concatenation for the nondeterministic case. Let \( (A', U', C') \) and \( (A'', U'', C'') \) be two \( \mathbb{K} \)-DetAPA and \# a symbol not in the alphabet of \( A' \). The main difference with the closure under concatenation of \( \mathbb{K} \)-APA is that the automaton \( A \) is constructed by adding \#-labeled transitions from the final states of \( A' \) to the initial state of \( A'' \). As \# is a symbol which is not in the alphabet of \( A' \), this preserves the determinism. □

Remark 4.9. These closures are effective in the sense that for every operation (e.g., intersection of \( \mathbb{K} \)-APA), there is an algorithm which computes it (e.g., given two \( \mathbb{K} \)-APA computes a \( \mathbb{K} \)-APA whose language is the intersection of the languages of the two). Also, we give the closure of \( L_{\text{DetAPA}} \) under pointed concatenation because we were not able to give a construction for the usual concatenation — we even conjecture that \( L_{\text{DetAPA}} \) is not closed under the usual concatenation.

We now give a large class of languages belonging to \( L_{\text{APA}} \) in two steps. First, we show that the language PAL of pointed palindromes, \( i.e., \text{PAL} = \{ w\#w^R \mid w \in \{a,b\}^* \} \), is recognized by a deterministic APA:

**Proposition 4.10.** \( \text{PAL} \in L_{\text{DetAPA}} \).

*Proof.* We sketch an \( \mathbb{N} \)-DetAPA \( (A, U, C) \) for PAL over \( \{0,1\}^* \) rather than \( \{a,b\} \).

The automaton \( A \) accepts words of the form \( u\#v \), with \( u, v \in \{0,1\}^* \). The affine functions compute the value of \( u \) (resp. \( v \)) seen as a binary number with the most (resp. least) significant bit first. Checking that those values are equal and that \(|u| = |v|\) is then the same as checking that \( u = v^R \). Formally, \( A = ([q_0, q_1], \{0,1,\#\}, \delta, q_0, \{q_1\}) \) where \( \delta \) is defined, together with the affine functions of \( U \), by:

\[
\begin{align*}
t_1 &= (q_0, 0, q_0) \text{ performs } (x, p, y, \ell) \mapsto (2x, 0, 0, \ell + 1), \\
t_2 &= (q_0, 1, q_0) \text{ performs } (x, p, y, \ell) \mapsto (2x + 1, 0, 0, \ell + 1), \\
t_3 &= (q_0, \#, q_1) \text{ performs } (x, p, y, \ell) \mapsto (x, 1, 0, \ell), \\
t_4 &= (q_1, 0, q_1) \text{ performs } (x, p, y, \ell) \mapsto (x, 2p, y, \ell - 1), \\
t_5 &= (q_1, 1, q_1) \text{ performs } (x, p, y, \ell) \mapsto (x, 2p, p + y, \ell - 1).
\end{align*}
\]

Now when reading a word \( u \in \{0,1\}^* \) from \( q_0 \), with \( x, p, y, \) and \( \ell \) starting at 0, the final value is \((x, 0, 0, |u|)\) where \( x \) is the value of \( u \) seen as a binary number with the most significant bit first. Reading \( u \) from \( q_1 \) with starting value \((x, 1, 0, \ell)\) leads to the value \((x, 2^{|u|}, y, \ell - |u|)\) with \( y \) the value of \( u \) seen as a binary number with the least significant bit first. Thus, letting \( C \) to be the semilinear set
\{(n, n', n, 0) \mid n, n' \in \mathbb{N}\} means that we check, on reading \(u \neq v\), that \(|u| = |v|\) and, in this case, that \(u = v^R\), hence \(L(A, U, C) = \text{PAL}\). \(\square\)

Now recall that a semi-AFL is a family of languages closed under nonerasing morphisms, inverse morphisms, intersection with a regular language, and union. Define \(\mathcal{M}_\cap(L)\) as the smallest semi-AFL containing \(L\) and closed under intersection. The closure properties of \(\mathcal{M}_\cap(\text{PAL})\) are implied by those of \(\mathcal{L}_{\text{APA}}\) (Prop. 4.8), hence:

**Proposition 4.11.** \(\mathcal{M}_\cap(\text{PAL}) \subseteq \mathcal{L}_{\text{APA}}\).

We do not know whether \(\mathcal{M}_\cap(\text{PAL}) \subseteq \mathcal{L}_{\text{DetAPA}}\) essentially since we do not know whether \(\mathcal{L}_{\text{DetAPA}}\) is closed under nonerasing morphisms, though we conjecture it is not.

The class \(\mathcal{M}_\cap(\text{PAL})\) contains a wide range of languages. First, the closure of PAL under nonerasing morphisms, inverse morphisms, and intersection with regular sets is the class of linear languages (e.g., [4]). In turn, adding closure under intersection permits to express the languages of nondeterministic multipushdown automata where in every computation, each pushdown store makes a bounded number of reversals (that is, going from pushing to popping) [3]; in particular, if there is only one such pushdown store, this corresponds to the ultralinear languages [10]. Further, as \(\mathcal{M}_\cap(\text{COPY}) \subseteq \mathcal{M}_\cap(\text{PAL})\) (e.g., [4]) this implies that \(\text{COPY} \in \mathcal{L}_{\text{APA}}\).

Next, we note that APA express only context-sensitive languages (CSL):

**Proposition 4.12.** \(\mathcal{L}_{\text{APA}} \subseteq \text{CSL}\).

*Proof.* Let \((A, U, C)\) be an \(\mathbb{N}\)-APA of dimension \(d\), we show that \(L(A, U, C) \in \text{NSPACE}[n]\) (which is equal to CSL [18]). Let \(A = (Q, \Sigma, \delta, q_0, F)\), and \(w = w_1 \ldots w_n \in \Sigma^*\). First, initialize \(\overline{v} \leftarrow \overline{0}\) and \(q \leftarrow q_0\). Iterate through the letters \(w_i\) of \(w\): on the \(i\)-th letter, choose nondeterministically a transition \(t = (q, w_i, q') \in \delta\). Update \(\overline{v}\) by setting \(\overline{v} \leftarrow U(t)\overline{v}\) and \(q \leftarrow q'\). Upon reaching the last letter of \(w\), accept \(w\) iff \(q \in F\) and \(\overline{v} \in C\).

We now bound the value of \(\overline{v}\). Let \(c\) be the greatest value appearing in any of the matrices or vectors in \(U_t\), for any \(t\). For a given \(\overline{v}\), let \(\text{max}\overline{v}\) be \(\max\{v_1, \ldots, v_d\}\). Then for any \(t\), \((U(t)\overline{v})_i \leq d \times (c \times \text{max}\overline{v}) + c\). Let \(\pi\) be a path, we then have that \((U(\pi(\overline{v})))_i \leq (c(d + 1))^{n-1} c\), thus the size of \(\overline{v}\) at the end of the algorithm is in \(O(n)\). Now note that, as \(C\) is semilinear, the language of the binary encoding of its elements is regular [26], and thus, checking \(\overline{v} \in C\) can be done in, say, logarithmic space. Hence the given algorithm is indeed in \(\text{NSPACE}[n]\). \(\square\)

We now show that \(\mathcal{L}_{\text{DetAPA}}\) is not closed under morphisms and we deduce new undecidability results. We rely on the following technical lemma that illustrates the subtle way in which a DetAPA can “perform the conjunction of an

---

5Brandenburg [4] defines PAL as \(\{w\overline{w}^R \mid w \in \{a, b\}^*\}\), where \(\overline{w}\) is the image of \(w\) by the morphism \(a \mapsto \overline{a}\) and \(b \mapsto \overline{b}\), for \(\overline{a}, \overline{b}\) two fresh symbols. We note that the results of [4] carry over with our definition of PAL.
unbounded number of conditions by maintaining a nonzero flag. Let SPACING be the language \( \{ (a^m \# a^n \#)^n \mid m, n \geq 0 \} \); note, for instance, that \( a\#a\#a\#a\# \) is in SPACING while \( a\#a\#a\#a\#a\#a\# \) is not.

**Lemma 4.13.** SPACING \( \in \mathcal{L}_{\text{DetAPA}} \).

**Proof.** Let \( \Sigma = \{ a, \# \} \), \( L_0 = \{ a^m \# a^n \mid m \geq 0 \} \ast \) and \( L_1 = L_0 \ast a\#a\ast \). Then:

\[
\text{SPACING} = \{ \varepsilon \} \cup [L_0 \cap a\# \cdot L_0 \cdot a\#] = \{ \varepsilon \} \cup [L_0 \cap a\# \cdot (L_1 \cap \Sigma^\ast \#)].
\]

We will show that \( L_0, L_1 \in \mathcal{L}_{\text{DetAPA}} \). This implies the result as follows. Since \( \mathcal{L}_{\text{DetAPA}} \) is closed under intersection (Fig. 1), \( L_1 \cap \Sigma^\ast \# \in \mathcal{L}_{\text{DetAPA}} \). By closure of \( \mathcal{L}_{\text{DetAPA}} \) under pointed concatenation (Prop. 4.8), \( a\# \cdot (L_1 \cap \Sigma^\ast \#) \in \mathcal{L}_{\text{DetAPA}} \). Applying closure properties again yields SPACING \( \in \mathcal{L}_{\text{DetAPA}} \). (Note that \( L_1 \) is needed to express SPACING because \( L_0 \in \mathcal{L}_{\text{DetAPA}} \) is not known to imply \( L_0 \ast a\# \in \mathcal{L}_{\text{DetAPA}} \).

We first construct a \( \mathbb{Q} \)-DetAPA \( D_0 \) on two registers \( x \) and \( y \) for \( L_0 \). As its underlying automaton, \( D_0 \) will have a two-state automaton \( A \) with initial and final state \( q_0 \). The 4 transitions of \( A \), and 4 affine functions \( \mathbb{Q}^2 \to \mathbb{Q}^2 \) assigned to these transitions, are:

\[
\begin{align*}
t_1 &= (q_0, a, q_0) \text{ performs } (x \ y) \mapsto (x+1 \ 2y), \\
t_2 &= (q_0, \#, q_1) \text{ performs } (x \ y) \mapsto (y), \\
t_3 &= (q_1, a, q_1) \text{ performs } (x \ y) \mapsto (x-1 \ 2y), \\
t_4 &= (q_1, \#, q_0) \text{ performs } (x \ y) \mapsto (0 \ x+y).
\end{align*}
\]

As usual, \( (x \ y) \) is \( (0 \ 0) \) initially. The constraint set \( C_0 \) for \( D_0 \) will be \( \{(0 \ 0)\} \) which is \( \mathbb{Q} \)-definable. (Only integers will ever appear in the counters; we use \( \mathbb{Q} \) rather than \( \mathbb{N} \) only to have access to negative integers). Surprisingly, this works.

We must argue that \( L(D_0) = L_0 \). We will write \( (q, (i \ j)_w) \) for the configuration of \( D_0 \) in which the state of \( A \) is \( q \in \{ q_0, q_1 \} \) and \( i \) and \( j \) are the contents of registers \( x \) and \( y \). For \( w \in \Sigma^\ast \), we will write \( (q, (i \ j)_w) \) for the configuration reached when \( A \) starts in configuration \( (q, (i \ j)) \) and reads \( w \). We need to prove two facts:

1. For any \( w \in L_0 \), \( (q_0, (0 \ 0)_w) = (q_0, (0 \ 0)) \);
2. For any \( w \in (a\#a\#a\#) \ast a\ast \) if \( (q_0, (0 \ 0)) \) then \( w \in L_0 \).

Fact (i) proves \( L_0 \subseteq L(D_0) \) because \( q_0 \) is final in \( A \) and \( (0 \ 0) \in C_0 \). Fact (ii) proves \( L(D_0) \subseteq L_0 \) because \( L(A) \) is seen to be \( (a\#a\#a\#) \ast a\ast \); hence fact (ii) states that any word that is in \( L(A) \) and that further sets \( (x \ y) \) to \( (0 \ 0) \) belongs to \( L_0 \).

To prove fact (i), let \( w = a^{m_1} \# a^{m_1} \# a^{m_2} \# a^{m_2} \# \ldots a^{m_k} \# a^{m_k} \# \) for \( k \geq 0 \). Any \( w \in L_0 \) has this form, and an induction on \( k \) shows that \( (q_0, (0 \ 0)_w) = (q_0, (0 \ 0)) \).

To prove fact (ii), we make the following claim, crucial to the operation of \( D_0 \):

**Claim:** for any \( u, v \in \Sigma^\ast \), if \( (q_0, (0 \ 0)_u \) sets \( y \neq 0 \) then \( (q_0, (0 \ 0))_w \) also sets \( y \neq 0 \).
The claim implies fact (ii) as follows. Let $w \in (a^*#a^*)^*a^i$ satisfy $(q_0, (\epsilon)_0)_w = (q_0, (\epsilon)_0)$. We must conclude $w \in L_0$. Let $w = a^{m_1}#a^{m_2}\ldots a^{m_{2k-1}}#a^{m_k}#a^i$ for some $k \geq 0$. By the Claim, every prefix of $w$ sets $y = 0$. Because reading every second # returns $A$ to $q_0$ and resets $x$ to $0$, we necessarily have

$$(q_0, (\epsilon)_0) = (q_0, (\epsilon)_0)_{a^{m_1}#a^{m_2}#} = (q_0, (\epsilon)_0)_{a^{m_3}#a^{m_4}#} = (q_0, (\epsilon)_0)_{a^{m_{2k-1}}#a^{m_{2k}}#},$$

and

$$(q_0, (\epsilon)_0)_w = (q_0, (\epsilon)_0)_{a^i} = (q_0, (i)_i).$$

By inspection of $A$, $(q_0, (\epsilon)_0) = (q_0, (\epsilon)_0)_{a^{m}#a^{m'}#}$ implies $m = m'$. Hence $m_1 = m_2, m_3 = m_4, \ldots, m_{2k-1} = m_{2k}$. Moreover, $(q_0, (\epsilon)_0)_w = (q_0, (\epsilon)_0)$ by assumption. Hence $i = 0$ and $w = a^{m_1}#a^{m_1}#\ldots a^{m_{2k-1}}#a^{m_{2k-1}}# \in L_0$, concluding fact (ii).

We now prove the Claim. Let $u \in \Sigma^*$ be such that $(q_0, (\epsilon)_0)_u$ sets $y \neq 0$. We need to show that for all $v \in \Sigma^*$, $(q_0, (\epsilon)_0)_uv$ also sets $y \neq 0$. Let $u = u_1u_2$ where $u_1$ is the shortest prefix of $u$ that sets $y \neq 0$. By inspection of $A$, $u_1 = u'a^i#a^j#$ for some $u' \in (a^*#a^*)^*$ such that $(q_0, (\epsilon)_0)_{u_1} = (q_0, (\epsilon)_0)_{a^i#a^j#} = (q_0, (\epsilon)_0)$ and $i \neq j$. We will prove by induction on the length of $w$ that for any $w \in \Sigma^*$, $(q_0, (\epsilon)_0)_w = (q, (\epsilon)_y)$ for some $q \in \{q_0, q_1\}$ and some $x_w, y_w \in \Omega$ such that $|y_w| \geq \max\{1, 2|x_w|\}$. This will complete the proof of the Claim since we can pick $w = u_2v$, and conclude that $(q_0, (\epsilon)_0)_uv = (q_0, (\epsilon)_0)_u = (q_0, (\epsilon)_0)_{u_2w} = (q_1, (\epsilon)_y)$ with $|y_u| \geq \max\{1, 2|x_u|\}$.

For the basis of the induction, let $w = \epsilon$. Then $(q_0, (\epsilon)_0)_\epsilon = (q_0, (\epsilon)_0)$. Now $|i - j| \geq 1 = \max\{1, 2 \times |0|\}$. For the inductive step, let $w \in \Sigma^n$ for some $n > 0$. Then $w = va$ or $w = v#$ and by induction, $(q_0, (\epsilon)_0)_v = (q, (\epsilon)_y)$ with $|y| \geq \max\{1, 2|x_v|\}$.

Case 1: $w = va$. Then $(q, (\epsilon)_0)_v = (q, (\epsilon)_y)$. If $x_v = 0$, then $|y_v| = |2y_v| \geq 2\max\{1, 2|x_v|\} = 2 = \max\{1, 2 \times |\pm 1|\} = \max\{1, 2|x_va|\}$. If $x_v \neq 0$, then $|y_v| = |2y_v| \geq 2\max\{1, 2|x_v|\} = 2(|x_v| + |x_v|) \geq 2(|x_v| + 1) \geq \max\{1, 2|x_v \pm 1|\} = \max\{1, 2|x_va|\}$.

Case 2: $w = v#$. If $t_2$ is the transition that consumed the last #, then $x_v = x_v#$ and $y_v = y_v#$ so the induction hypothesis immediately yields $|y_v| \geq \max\{1, 2|x_v|\}$. So let $t_4$ be the transition that consumed the last #.
Then \((q, (0, 0))_{v^\#} = (q, (0, 0))\). Now \(|y_{va}| = |x_v + y_v| \geq |y_v| - |x_v| \geq \max\{1, 2|x_v|\} \geq \max\{1, |x_v|\} \geq 1 = \max\{1, 2 \times |0|\} = \max\{1, 2 \times |x_v^\#|\}\). This concludes the proof of the Claim and the proof that \(L(D_0) = L_0\).

We have yet to construct a \(\mathbb{Q}\)-DetAPA \(D_1\) for \(L_1\). The automaton underlying \(D_1\) will be \(A\), as above, except that the final state will be \(q_1\) rather than \(q_0\). The affine functions associated with the transitions remain the same. The constraint set \(C_1\) will be \(\{r_q : r \in \mathbb{Q}\}\) and it is \(\mathbb{Q}\)-definable. We need to prove the following facts:

(iii) \(\forall w \in L_1, (q_0, (0, 0))_w = (q_1, (i)^i)\) for some \(i \in \mathbb{Q}\);

(iv) \(\forall w \in (a^*#a^*#)^*a^*#a^*, (q_0, (0, 0))_w = (q_1, (i)^i)\) then \(w \in L_1\).

Fact (iii) follows from fact (i) since any \(w \in L_1\) is of the form \(w = ua^t#a^j\) with \(u \in L_0\), so that \((q_0, (0, 0))_w = (q_0, (0, 0))a^t#a^j = (q_1, (i-j)^j)\). To prove fact (iv), let \(w \in (a^*#a^*#)^*a^*#a^*\) satisfy \((q_0, (0, 0))_w = (q_1, (x_0^x))\). By the Claim above, every prefix of \(w\) sets \(y = 0\). By inspection of \(A\), some suffix \(a^t#a^j\) of \(w\) must have sent \(A\) to state \(q_1\), that is, \(w = ua^t#a^j\) with \((q_0, (0, 0))_u = (q_0, (0, 0))\) and \(x_w = i - j\). But then, \(u \in L_0\) by fact (ii) and thus \(w \in L_1\). This concludes the proof that \(L(D_1) = L_1\) and proves the lemma. \(\square\)

**Lemma 4.14.** Given a Turing machine \(M\), we can construct a morphism \(h\) and a DetAPA \(D\) such that \(L(M) = h(L(D))\).

**Proof.** We adapt [1], Theorem 1. With no loss of generality, we assume that \(M\) is a one-tape Turing machine that accepts by halting and makes an odd number of moves on any accepting computation. Let \(L_1\) (resp. \(L_2\)) be the set of strings

\[
ID_0#ID_2# \ldots #ID_{2k}$$(ID_{2k+1})^R# \ldots #(#ID_3)^R(#ID_1)^R# \tag{4.1}
\]

such that \(ID_i\), \(0 \leq i \leq 2k + 1\), are instantaneous descriptions of \(M\) padded with the blank symbol \(b\) to a common length \(\ell\), \(ID_0 = [w_1]_{q_0}w_2 \ldots w_n b^\ell n\) codes the initial configuration of \(M\) ([w_1]_{q_0} \text{ is considered as a single letter, and, w_1 = b when the word w = w_1w_2 \ldots w_n \in } \Sigma^* \text{ input to M is } \varepsilon\), \(ID_{2k+1}\) codes an accepting configuration and for \(0 \leq i \leq k\), \(ID_{2i+1}\) (resp. for \(0 < i \leq k\), \(ID_{2i}\) codes the configuration which would be reached in one step from configuration \(ID_{2i}\) (resp. \(ID_{2i+1}\)). Each \(ID_i\) other than \(ID_0\) is coded using an alphabet \(\Gamma\) disjoint from \(\Sigma \cup \{[\sigma]\} \mid \sigma \in \Sigma \} \cup \{[b]\}\). It should be clear that \(w \in L(M)\) iff \(w \in h(L_1 \cap L_2)\) where for every \(\sigma \in \Sigma\) and every \(\gamma \in \Gamma\),

\[
h([\sigma]) = h(\sigma) = \sigma \text{ and } h([b]_{q_0}) = h(b) = h(\#) = h($) = h(\gamma) = \varepsilon.
\]

To complete the proof, we claim that \(L_1 \cap L_2 \in L_{\text{DetAPA}}\) in the effective sense. Since \(L_{\text{DetAPA}}\) is closed under intersection in that sense (Fig. 1), it suffices to show that \(L_1 \in L_{\text{DetAPA}}\) and \(L_2 \in L_{\text{DetAPA}}\). We first show how to construct a DetAPA recognizing \(L_1\). We will construct an N-DetAPA \(D_1\) able to handle only the words of the form (4.1) in which the distance between any two consecutive
symbols # or $ is $|ID_0|$. Handling only those words will be sufficient because the language $L_1$ can then be expressed as $L_1 = g^{-1} (\text{SPACING}) \cap L(D_1)$ where $g$ is the morphism mapping both # and $\$ to # and mapping every other symbol to the letter $a$. Since Lemma 4.13 shows SPACING $\in \mathcal{L}_{\text{DetAPA}}$ and since $\mathcal{L}_{\text{DetAPA}}$ is closed under intersection and inverse morphisms in the effective sense (Fig. 1), a DetAPA for $L_1$ can be constructed from $D_1$.

So we now describe $D_1$. Let $m$ be the size of the alphabet $\Gamma$. We argue as if $ID_0$ in (4.1) were coded over the same alphabet $\Gamma$ used to code $ID_i$ for $0 < i \leq 2k + 1$, since a finite automaton can easily adjust for this. Our strategy will extend the strategy used to construct an N-DetAPA for pointed palindromes (Prop. 4.10) as follows. As $D_1$ reads the prefix $ID_0 \# ID_2 \# \ldots \# ID_{2k}$ of (4.1), $D_1$ will internally translate that prefix into $ID_1 ID_3 \ldots ID_{2k+1}$ and will treat the latter as the prefix $u$ of a pointed palindrome $u$$. As $D_1$ processes $u$, $D_1$ builds in a register the natural number having $u$ as its $m$-ary representation with the most significant bit first (as in Prop. 4.10, where $m$ was 2). Then $D_1$ encounters $\$$ and begins to do the matchup with the suffix $(ID_{2k+1})^R \# \ldots \# (ID_3)^R \# (ID_1)^R \#$ of (4.1). $D_1$ does this matchup by internally translating this suffix into $(ID_{2k+1})^R \ldots (ID_3)^R (ID_1)^R = (ID_1 ID_3 \ldots ID_{2k+1})^R = u^R$. As $D_1$ processes this suffix, $D_1$ computes in a register the natural number having the suffix as its $m$-ary representation, with the least significant bit first this time (again as in Prop. 4.10, now with $m$ rather than 2). We set $D_1$ to accept iff reading (4.1) indeed leads to $u$$. With $ID_{2k+1}$ final. Two subtleties are worth mentioning concerning processing the prefix. First, when processing $ID_{2i}$, $D_1$ always reads one symbol ahead of position $p$ to determine the proper symbol at position $p$ in $ID_{2i+1}$, to account for the input head of $M$ possibly moving left from position $p + 1$ to position $p$. Second, $D_1$ rejects immediately if $ID_0$ is not a legal coding of an initial configuration of $M$ or if another $ID_i$ in the prefix contains two input head symbols. This completes the operational description of $D_1$. The formal definition $(A_1, U_1, C_1)$ of $D_1$ thus needs to implement these operations. The $N$-definable set $C_1$ is the set $C \subseteq \mathbb{N}$ given in the Proof of Proposition 4.10 but adapted to handle $m$-ary representation rather than binary. The affine functions assigned to the transitions of $A_1$ are the identity function together with the five (adapted) functions assigned to the transitions $t_1, t_2, t_3, t_4, t_5$ from the Proof of Proposition 4.10: transitions performing the bookkeeping operations of $A_1$ (such as when $A_1$ processes the symbol $\#$) will be assigned the identity function, and transitions that discover the next PAL symbol are assigned the affine transformation prescribed by Proposition 4.10 on reading that symbol (with the understanding that reading $\$$ here corresponds to reading $\#$ there).

The strategy to construct an N-DetAPA $D_2$ recognizing $L_2$ is of course similar. But now, since $ID_2$ (for example) does not uniquely determine $ID_1$, the prefix of (4.1) is handled by $D_2$ as the suffix of (4.1) was handled by $D_1$. Specifically, $D_2$ internally translates the prefix $ID_0 \# ID_2 \# \ldots \# ID_{2k}$ into $u = ID_1 ID_4 \ldots ID_{2k}$ and stores the $m$-ary number $u$ in a register, with the most significant bit first. Then $D_2$ encounters $\$, discards $(ID_{2k+1})^R$ and internally translates the remainder $(ID_{2k-1})^R \# \ldots \# (ID_3)^R \# (ID_1)^R \#$ of the suffix into
(ID_{2k})^R \ldots (ID_4)^R (ID_2)^R = (ID_2 ID_4 \ldots ID_{2k})^R = u^R. As did D_1 when reading
the prefix, D_2 needs to look ahead by one symbol while processing the suffix. The
matchup with u^R is otherwise done by D_2 just as the matchup was done by D_1.
This completes the description of D_2 and proves the lemma. □

**Corollary 4.15.** Neither $L_{APA}$ nor $L_{DetAPA}$ is closed under morphisms.

**Proof.** Given a Turing machine $M$, we can construct a morphism $h$ and a DetAPA
(and a fortiori an APA) $D$ such that $L(M) = h(L(D))$. If either $L_{APA}$ or $L_{DetAPA}$
were closed under morphisms, then the language $h(L(D))$ would be the language
of an APA. But the language of any APA is context-sensitive (Lem. 4.12), thus
decidable, so we could decide $L(M)$. □

**Corollary 4.16.** The emptiness, universality, inclusion, finiteness, and regularity
problems are undecidable for DetAPA.

**Proof.** (Emptiness, universality, and inclusion). Given a Turing machine $M$ with
$L(M) \subseteq \Sigma^*$, let $h$ be the morphism and $D$ the DetAPA provided by Lemma 4.14.
For any $x \in \Sigma^*$, $x \in L(M)$ iff $x = h(y)$ for some $y \in L(D)$ iff $L(D) \cap h^{-1}(x)$ is
nonempty. Now $\{x\} \in L_{DetAPA}$ and $L_{DetAPA}$ is closed (in the effective sense) under
inverse morphisms and intersection (Fig. 1). Hence we can construct a DetAPA
for $L(D) \cap h^{-1}(x)$ and deciding its emptiness would decide $x \in L(M)$. Moreover,
$\mathbb{K}$-DetAPA being closed under complement (in the effective sense), the emptiness
problem reduces to the universality problem. Finally, the undecidability of empti-
ness implies that we cannot decide if the language of a $\mathbb{K}$-DetAPA is included in
the empty set.

(Finiteness and regularity [pointed out by Andreas Krebs]). Let $L \subseteq \Sigma^*$ be
a language of $L_{DetAPA}$, and let $\# \not\in \Sigma$. Then $L \cdot \{\#a^n b^n \mid n \in \mathbb{N}\}$ is in $L_{DetAPA}$
effectively constructible from the given DetAPA, as a pointed concatenation
(Prop. 4.8). Its language is finite iff it is regular iff $L$ is empty. □

**Remark 4.17.** None of these results allow us to conclude that $L_{DetAPA}$ and $L_{APA}$
are different, though we conjecture they are. One argument supporting this con-
jecture is the fact that DetAPA do not need their automaton: we can encode the
transition function of an automaton within the affine functions, showing that any
language of $L_{DetAPA}$ can be expressed using a two-state DetAPA.

5. Parikh automata on letters

The PA on letters requires that the “weight” of a transition depends only on
the input letter from $\Sigma$ triggering the transition. In a way similar to the CA
characterization of PA, we characterize PA on letters solely in terms of automata
over $\Sigma$ and semilinear sets. We further give expressiveness and closure properties
of the classes of languages that arise.
**Definition 5.1** (Parikh automaton on letters). A *Parikh automaton on letters* (LPA) is a PA \((A, C)\) where whenever \((a, \overrightarrow{v})\) and \((a, \overrightarrow{v'})\) are labels of some transitions in \(A\), then \(\overrightarrow{v} = \overrightarrow{v'}\). We write \(\mathcal{L}_{\text{LPA}}\) (resp. \(\mathcal{L}_{\text{DetLPA}}\)) for the class of languages recognized by LPA (resp. LPA which are DetPA).

First, we prove that \(\mathcal{L}_{\text{LPA}}\) and \(\mathcal{L}_{\text{DetLPA}}\) coincide:

**Theorem 5.2.** \(\mathcal{L}_{\text{LPA}} = \mathcal{L}_{\text{DetLPA}}\).

**Proof.** Let \((A, C)\) be a LPA. Without loss of generality, we can consider \(A = (Q, \Sigma \times D, \delta, q_0, F)\) to be deterministic (this does not imply that the PA is deterministic). Now let \(t, t' \in \delta\) with \(t = (p, (a, \overrightarrow{v}))\) and \(t' = (p, (a, \overrightarrow{v'}))\). The fact that \((A, C)\) is a LPA implies that \(\overrightarrow{v} = \overrightarrow{v'}\), and \(A\) being deterministic, this implies that \(q = q'\), and in turn that \(t = t'\). Thus \((A, C)\) is a DetPA. 

For \(L \subseteq \Sigma^*\) and \(C \subseteq \mathbb{N}^{\left|\Sigma\right|}\), recall that \(L |_{C} = \{w \in L \mid \Phi(w) \in C\}\). Then:

**Proposition 5.3.** Let \(L \subseteq \Sigma^*\) be a language. The following are equivalent:

1. \(L \in \mathcal{L}_{\text{LPA}}\);
2. there exist a regular language \(R \subseteq \Sigma^*\) and a semilinear set \(C \subseteq \mathbb{N}^{\left|\Sigma\right|}\) such that \(R |_{C} = L\).

**Proof.**

1. \(\Rightarrow\) 2. Let \((A, C)\) be a LPA which is a DetPA over the alphabet \(\{a_1, \ldots, a_n\}\). For \(1 \leq i \leq n\), let \(\overrightarrow{v}\) be the only vector appearing as the label \((a_i, \overrightarrow{v})\) of a transition in \(A\). Define \(C' \subseteq \mathbb{N}^n\) by \((x_1, \ldots, x_n) \in C' \iff \sum_i x_i \times \overrightarrow{v} \in C\). Then let \(w \in \Sigma^*\) and \(\omega\) be the word which can be read from the initial state of \(A\) with \(\Psi(\omega) = w\). We have that \(\sum_i \Phi(w)_i \times \overrightarrow{v} = \Phi(\omega)\), and thus \(w \in L(A, C)\) iff \(w \in \Psi(L(A)) |_{C'}\).

2. \(\Rightarrow\) 1. Let \(R \subseteq \{a_1, \ldots, a_n\}^*\) be a regular language and \(C \subseteq \mathbb{N}^n\) be a semilinear set. Let \(A\) be an automaton for \(R\), and change each transition label \(a_i\) in \(A\) by \((a_i, \overrightarrow{v})\). Now for \(\omega \in L(A)\), \(\Phi(\omega) = \Phi(\Psi(\omega))\) and thus \((A, C)\) is a LPA with language \(R |_{C}\).

The following property will be our central tool for showing nonclosure results:

**Lemma 5.4.** Let \(L \in \mathcal{L}_{\text{LPA}}\). For any regular language \(E\):

\[
L \cap E \text{ is not regular } \Rightarrow (\exists w \in E)[c(w) \cap L = \emptyset].
\]

**Proof.** Let \(R \subseteq \Sigma^*\) be a regular language and \(C \subseteq \mathbb{N}^{\left|\Sigma\right|}\) be a semilinear set. Define \(L = R |_{C}\). Let \(E\) be a regular language such that \(L \cap E\) is not regular. As \(L \subseteq R\), we have \((L \cap E) \subseteq (R \cap E)\). The left hand side being non regular, those two sets differ. Thus, let \(w \in (R \cap E)\) such that \(w \notin L \cap E\), we have \(w \notin L\). Hence, \(w \in (R \setminus L)\), which implies that \(\Phi(w) \notin C\), and in turn, \(c(w) \cap L = \emptyset\). 

\(\square\)
Proposition 5.5. (1) $L_{LPA}$ is not closed under union, complement, concatenation, nonerasing morphisms, and starring; (2) $L_{LPA}$ is closed under intersection, commutative closure, and inverse morphisms.

Proof.
(1) Let $L = \{a^m b^n \mid m, n \in \mathbb{N} \land m \neq n\}$ be a language of LPA. (Union). Suppose $L' = L \cup a^+ b^2 \in L_{LPA}$. Let $E$ be the regular language $(a^+ b^+)$. By the pumping lemma, $L' \cap E$ is not regular, thus Lemma 5.4 states there exists $w \in E$ such that $c(w) \cap L' = \emptyset$. But $u = b^{|w|} a^{|w|} a \in c(w)$ and $u \in L'$, a contradiction, thus $L' \notin L_{LPA}$. (Complement). We note that $L'$ is the complement in $\{a, b\}^*$ of $\{a^n b^n \mid n \in \mathbb{N}\}$, which is the language of an LPA. (Concatenation). Suppose $L^2 \in L_{LPA}$. Again, as $L^2 \cap E^2$ is not regular, Lemma 5.4 asserts that there exists $w \in E^2$ such that $c(w) \cap L^2 = \emptyset$. But $a^{|w|} a^0 b^0 a^{|w|} b^0 \in c(w) \cap L^2$, a contradiction, thus $L^2 \notin L_{LPA}$. (Nonerasing morphism). We note that $L^2$ is the image of the LPA language $\{a^1 b^1 a^2 b^2 \mid m \neq n \land r \neq s\}$ by the nonerasing morphism $h(a_i) = a, h(b_i) = b, i \in \{1, 2\}$. Also, by the very definition of constrained automata (Def. 3.3), each language of $L_{LPA}$ is the image by a nonerasing morphism of a language of $L_{LPA}$, but the two classes are different. (Starring). The proof of the nonclosure under starring of $L_{PA}$ (Prop. 3.17) shows that the starring of $\{a^n b^n \mid n \in \mathbb{N}\}$ is not in $L_{PA}$, thus not in $L_{LPA}$.

(2) Let $R, R' \subseteq \Sigma^*$ be two regular languages and let $C, C' \subseteq \mathbb{N}^{\Sigma}$ be two semilinear sets. (Intersection). Note that $(R \upharpoonright C) \cap (R' \upharpoonright C') = (R \cap R') \upharpoonright C \cap C'$, the latter being a language of $L_{LPA}$. (Commutative closure). Likewise, note that $c(R \upharpoonright C) = \Sigma^* \upharpoonright C \cap \Phi(R)$, which is in $L_{LPA}$ since $\Phi(R)$ is effectively semilinear by Parikh’s theorem. (Inverse morphism). Let $h: \{a_1, \ldots, a_n\}^* \rightarrow \Sigma^*$ be a morphism, and let $C^h = \{\bar{v} \in \mathbb{N}^n \mid \sum_i x_i \times \Phi(h(a_i)) \in C\}$. Then we claim that $h^{-1}(R \upharpoonright C) = (h^{-1}(R)) \upharpoonright C^h$, which concludes the proof as $h^{-1}(R)$ is regular and $C^h$ is semilinear. Indeed, let $w \in h^{-1}(R \upharpoonright C)$, then $w \in h^{-1}(R)$ and $\Phi(h(w)) \in C$, the latter implying that $\sum_i |w|_{a_i} \times \Phi(h(a_i)) \in C$, and thus, $\Phi(w) \in C^h$; in particular, if a letter $a$ is such that $h(a) = \varepsilon$, it is discarded when looking at the Parikh image of $h(w)$. Conversely, if $w \in h^{-1}(R \upharpoontright C^h)$ then $h(w) \in R$ and $\Phi(h(w)) = \sum_i |w|_{a_i} \times \Phi(h(a_i)) \in C$, thus $h(w) \in R \upharpoonright C$, implying that $w \in h^{-1}(R \upharpoonright C)$.

6. Conclusion

Figures 1 and 2 in our introductory section summarize the current state of knowledge concerning the PA and its variants studied here.

An intriguing question is whether there are context-free or context-sensitive languages outside $L_{APA}$. How difficult is that question? How about $L_{DetAPA}$? We have been unable to locate the latter class meaningfully. In particular, can $L_{DetAPA}$ be separated from $L_{APA}$?

Several questions thus remain open concerning the poorly understood (and possibly overly powerful) APA model. But surely we expect testing a LPA or a DetPA
for regularity to be decidable. How can regularity be tested for these models? One avenue for future research towards this goal might be characterizing $\mathcal{L}_{\text{DetPA}}$ along the lines of algebraic automata theory.

Acknowledgements. The first author thanks L. Beaudou, M. Kaplan, and A. Lemaître for stimulating discussions and comments on early versions of this paper. We further thank the anonymous referees for their critical comments and especially for pointing out a flawed claim made in an earlier version of this work concerning DetAPA.
