Abstract. We investigate extensions of CTL allowing to express quantitative requirements about an abstract notion of time in a simple discretetime framework, and study the expressive power of several relevant logics. When only subscripted modalities are used, polynomial-time model checking is possible even for the largest logic we consider, while introducing freeze quantifiers leads to a complexity blow-up.

1 Introduction

Temporal logic is widely used as a formal language for specifying the behaviour of reactive systems (see [Eme90]). This approach allows model checking, i.e. the automatic verification that a finite state system satisfies its expected behavourial specifications. The main limitation to model checking is the state-explosion problem but, in practice, symbolic model checking techniques [BCM⁺92] have been impressively successful, and model checking is now commonly used in the design of critical reactive systems.

Real-time. While temporal logics only deal with "before and after" properties, *real-time temporal logics* and more generally *quantitative temporal logics* aim at expressing quantitative properties of the time elapsed during computations. Popular real-time logics are based on timed transition systems and appear in several tools (e.g., HyTech, Uppaal, Kronos). The main drawback is that model checking is expensive [ACD93,AL99].

Efficient model checking. By contrast, some real-time temporal logics retain usual discrete Kripke structures as models and allow to refer to quantitative information with "bounded" modalities such as " $AF_{\leq 10} A$ " meaning that A will inevitably occur in at most 10 steps. A specific aspect of this framework is that the underlying Kripke structures have no inherent concept of time. It is the designer of the Kripke structure who decides to encode the flow of elapsing time by this or that event, so that the temporal logics in use are more properly called quantitative temporal logics than real-time logics. [EMSS91] showed that RTCTL (i.e. CTL plus bounded modalities " $A_{-}U_{\leq k}$ -" and " $E_{-}U_{\leq k}$ -" in the Kripke structure framework) still enjoys the bilinear model checking time complexity of CTL. Our contribution. One important question is how far can one go along the lines of RTCTL-like logics while still allowing efficient model checking? Here we study two quantitative extensions of CTL, investigate their expressive power and evaluate the complexity of model checking.

The first extension, called $TCTL_s$, s for "subscripts", is basically the most general logic along the lines of the RTCTL proposal : it allows combining " $\leq k$ ", " $\geq k$ " and "= k" (so that modalities counting w.r.t. intervals are possible). We show this brings real improvements in expressive power, and model checking is still in polynomial time. This extends results for RTCTL beyond the increased expressivity: we use a finer measure for size of formula (EF_{=k} has size in $O(\log k)$ and not k) and do not require that one step uses one unit of time.

The second extension, called $TCTL_c$, c for "clocks", uses formula clocks, a.k.a. freeze quantifiers [AH94], and is a more general way of counting events. $TCTL_c$ can still be translated directly into CTL but model checking is expensive.

The results on expressive power formalize natural intuitions which (as far as we know) have never been proven formally, even in the dense time framework¹. Furthermore, in our discrete time framework our results on expressive power must be stated in terms of how succinctly can one logic express this or that property. Such proofs are scarce in the literature (one example is [Wil99]).

Related work. $TCTL_s$ and $TCTL_c$ are similar to (and inspired from) logics used in dense real-time frameworks (though, in the discrete framework we use here, their behaviour is quite different). Our results on complexity of model checking build on ideas from [DS98,KVW98,AL99,ET99].

Other branching-time extensions of *RTCTL* have been considered. Counting with regular patterns makes model checking intractable [ET97]. Merging different time scales makes model checking NP-complete [ET99]. Allowing parameters makes model checking exponential in the number of parameters [ET99].

Another extension with freeze variables can be found in [YMW97] where richer constraints on number of occurrences of events can be stated (rending satisfiability undecidable). On the other hand, the "until" modality is not included and the expressive power of different kinds of constraints is not investigated.

Plan of the paper. We introduce the basic notions and definitions in § 2. We discuss expressive power in § 3 and model checking in § 4. We assume the reader is familiar with standard notions of branching-time temporal logic (see [Eme90]) and structural complexity (see [Pap94]). Complete proofs appear in a full version of the paper, available from the authors.

2 CTL + discrete time

We write \mathbb{N} for the set of natural numbers, and $AP = \{A, B, \ldots\}$ for a finite set of *atomic propositions*. Temporal formulae are interpreted over states in Kripke structures. Formally,

¹ See e.g. the conjecture at the end of [ACD90] which becomes an unproved statement in [ACD93].

Definition 2.1. A Kripke structure (a "KS") is a tuple $S = \langle Q_S, R_S, l_S \rangle$ where $Q_S = \{q_1, \ldots\}$ is a non-empty set of states, $R_S \subseteq Q_S \times Q_S$ is a total transition relation, and $l_S : Q_S \to 2^{AP}$ labels every state with the propositions it satisfies.

Below, we drop the "S" subscript in our notations whenever no ambiguity will arise. A computation in a KS is an infinite sequence π of the form $q_0q_1 \ldots$ s.t. $(q_i, q_{i+1}) \in R$ for all $i \in \mathbb{N}$. For $i \in \mathbb{N}$, $\pi(i)$ (resp. $\pi_{|i|}$) denotes the *i*-th state, q_i (resp. *i*-th prefix: q_0q_1, \ldots, q_i). We write $\Pi(q)$ for the set of all computations starting from q. Since R is total, $\Pi(q)$ is never empty.

The flow of time. We assume a special atomic proposition $tick \in AP$ that describes the elapsing of time in the model. The intuition is that states labeled by *tick* are states where we observe that time has just elapsed, that the *clock just ticked*. Equivalently, we can see all transitions as taking 1 time unit if they reach a state labeled by *tick*, and as being instantaneous otherwise ². In pictures, we use different grey levels to distinguish *tick* states from non-*tick* ones.

Given a computation $\pi = q_0 q_1 \dots$ and $i \ge 0$, $\mathsf{Time}(\pi_{|i|})$ denotes $|\{j \mid 0 < j \le i \land tick \in l(q_j)\}|$, the time it took to reach q_i from q_0 along π .

$2.1 \quad TCTL_{s}$

Syntax. $TCTL_s$ formulae are given by the following grammar:

 $\varphi, \psi ::= \neg \varphi \mid \varphi \land \psi \mid \mathsf{EX}\varphi \mid \mathsf{E}\varphi\mathsf{U}_I \psi \mid \mathsf{A}\varphi\mathsf{U}_I \psi \mid A \mid B \mid \dots$

where I can be any finite union $[a_1, b_1[\cup \cdots \cup [a_n, b_n]]$ of disjoint integer intervals with $0 \le a_1 < b_1 < a_2 < b_2 < \cdots > a_n < b_n \le \omega$.

Standard abbreviations include $\top, \bot, \varphi \lor \psi, \varphi \Rightarrow \psi, \ldots$ as well as $\mathsf{EF}_I \varphi$ (for $\mathsf{E} \top \mathsf{U}_I \varphi$), $\mathsf{AF}_I \varphi$ (for $\mathsf{A} \top \mathsf{U}_I \varphi$), $\mathsf{EG}_I \varphi$ (for $\neg \mathsf{AF}_I \neg \varphi$), and $\mathsf{AG}_I \varphi$ (for $\neg \mathsf{EF}_I \neg \varphi$).

Moreover we let $U_{\leq k}$ stand for $U_{[0,k[}, U_{>k}$ for $U_{[k+1,\omega[}, \text{and } U_{=k}$ for $U_{[k,k+1[}$. The usual *CTL* operators are included since the usual U corresponds to $U_{\leq \omega}$.

Semantics. Figure 1 defines when a state q in some KS S, satisfies a $TCTL_s$ formula φ , written $q \models \varphi$, by induction over the structure of φ .

We let $TCTL_s[<]$, $TCTL_s[<,=]$, etc. denote the fragments of $TCTL_s$ where only simple constraints using only < (resp. < or =, etc.) are allowed. E.g., RTCTL is $TCTL_s[<]$ (with the proviso that our KS's have *tick*'s).

$2.2 \quad TCTL_{c}$

 $TCTL_c$ uses freeze quantifiers [AH94]. Here "clocks" are introduced in the formula, set to zero when they are bound, and can be referenced "later" in arbitrary ways. This standard construct gives more flexibility than subscripts.

² Thus KS's with *tick*'s can be seen as *discrete timed structures*, i.e. KS's where edges $(q, q') \in R$ are labeled by a natural number: the time it takes to follow the edge. While discrete timed structures are more natural, KS's with *tick* are an essentially equivalent framework where technicalities are simpler since they do not need labels on the edges.

 $\begin{array}{ll} q \models A & \text{iff } A \in l(q), \\ q \models \neg \varphi & \text{iff } q \not\models \varphi, \\ q \models \varphi \land \psi & \text{iff } q \models \varphi \text{ and } q \models \psi, \\ q \models \mathsf{EX}\varphi & \text{iff there exists } \pi \in \Pi(q) \text{ s.t. } \pi \models \mathsf{X}\varphi, \\ q \models \mathsf{E}\varphi\mathsf{U}_I \ \psi & \text{iff there exists } \pi \in \Pi(q) \text{ s.t. } \pi \models \varphi\mathsf{U}_I \ \psi \\ q \models \mathsf{A}\varphi\mathsf{U}_I \ \psi & \text{iff for all } \pi \in \Pi(q), \text{ we have } \pi \models \varphi\mathsf{U}_I \ \psi \\ \pi \models \mathsf{X}\varphi & \text{iff } \pi(1) \models \varphi, \\ \pi \models \varphi\mathsf{U}_I \ \psi & \text{iff there exists } i \ge 0 \text{ s.t. } \mathsf{Time}(\pi_{|i}) \in I \\ & \text{and } \pi(i) \models \psi \text{ and } \pi(j) \models \varphi \text{ for all } 0 \le j < i, \end{array}$

Syntax. For a set $Cl = \{x, y, \ldots\}$ of clocks, $TCTL_c$ formulae are given by the following grammar:

$$\varphi, \psi ::= \neg \varphi \mid \varphi \land \psi \mid \mathsf{EX}\varphi \mid \mathsf{E}\varphi \mathsf{U}\psi \mid \mathsf{A}\varphi \mathsf{U}\psi \mid x \underline{in} \varphi \mid x \sim k \mid A \mid B \mid \dots$$

where $\sim \in \{=, \leq, <, \geq, >\}$ and $k \in \mathbb{N}$. Constraints referring to clocks are restricted to the simple form $x \sim k$, in the spirit of $TCTL_s$.

An occurrence of a formula clock x in some $x \sim k$ is *bound* if it is in the scope of a " $x \underline{in}$ " freeze quantifier, otherwise it is *free*. A formula is *closed* if it has no free variables. Only closed formulae express properties of states in KS's.

Semantics. $TCTL_c$ formulae are interpreted over a state of a KS S together with a valuation $v: Cl \to \mathbb{N}$ of the clocks free in φ .

 $\begin{array}{ll} q, v \models A & \text{iff } A \in l(q), \\ q, v \models \neg \varphi & \text{iff } q, v \not\models \varphi, \\ q, v \models \varphi \land \psi & \text{iff } q, v \models \varphi \text{ and } q, v \models \psi, \\ q, v \models \mathsf{EX}\varphi & \text{iff there exists } \pi \in \Pi(q) \text{ s.t. } \pi, v \models \mathsf{X}\varphi \\ q, v \models \mathsf{E}\varphi \mathsf{U}\psi & \text{iff there exists } \pi \in \Pi(q) \text{ s.t. } \pi, v \models \varphi \mathsf{U}\psi \\ q, v \models \mathsf{A}\varphi \mathsf{U}\psi & \text{iff for all } \pi \in \Pi(q) \text{ we have } \pi, v \models \varphi \mathsf{U}\psi \\ q, v \models x \sim k & \text{iff } v(x \leftarrow 0] \models \varphi \\ q, v \models x \sim k & \text{iff } v(1), v + d \models \varphi \text{ with } d = \mathsf{Time}(\pi_{|1}) \\ \pi, v \models \varphi \mathsf{U}\psi & \text{iff there exists } i \geq 0 \text{ s.t. } \pi(i), v + d_i \models \psi \text{ and} \\ \pi(j), v + d_j \models \varphi \text{ for all } 0 \leq j < i \text{ (where } d_l \stackrel{\text{def}}{=} \mathsf{Time}(\pi_{|l})) \end{array}$

Figure 2 defines when $q, v \models \varphi$ in some KS S by induction over the structure of φ . For $m \in \mathbb{N}, v + m$ denotes the valuation which maps each clock $x \in Cl$ to the value v(x)+m, and $v[x \leftarrow 0]$ is v where now x evaluates to 0.

Clearly the $TCTL_s$ operators can be defined with $TCTL_c$ operators:

$$\mathsf{E}\varphi\mathsf{U}_{I}\;\psi\stackrel{\mathrm{def}}{=}x\;\underline{\mathsf{in}}\;\left(\mathsf{E}\varphi\mathsf{U}(I(x)\wedge\psi)\right)\qquad \mathsf{A}\varphi\mathsf{U}_{I}\;\psi\stackrel{\mathrm{def}}{=}x\;\underline{\mathsf{in}}\;\left(\mathsf{A}\varphi\mathsf{U}(I(x)\wedge\psi)\right)$$

where, for I of the form $[a_1, b_1[\cup \cdots \cup [a_n, b_n[, I(x)]]$ denotes the *clocks constraint* $\bigvee_{i=1}^n ((a_i \leq x) \land (x < b_i))$. Hence $TCTL_s$ can be seen as a fragment of $TCTL_c$ where

only one formula clock is allowed (and used in restricted ways).

A standard observation for logics such as $TCTL_c$ is that the actual values recorded in v are only relevant up to a certain point depending on the formula at hand. Let M_{φ} denote the largest constant appearing in φ (largest k in the " $x \sim k$ "'s) and, for $m \in \mathbb{N}$, let $v \equiv_m v'$ when for any $x \in Cl$, either v(x) = v'(x) or v(x) > m < v'(x) (i.e. v and v' agree, or are beyond m).

Lemma 2.2. If $v \equiv_m v'$ and $m \geq M_{\varphi}$, then $q, v \models \varphi$ iff $q, v' \models \varphi$.

Proof. Easy induction over the structure of φ , using the fact that $v \equiv_m v'$ entails $v + k \equiv_m v' + k$ and $v[x \leftarrow 0] \equiv_m v'[x \leftarrow 0]$.

Remark 2.3. A related property is used by Emerson et al. in their study of *RTCTL*: when checking whether $q \models \varphi$ inside some KS with |Q| = m states, it is possible to replace by m any constant k larger than m in the subscripts of φ . We emphasize that this property does not hold for $TCTL_s[=]$ (it does hold for $TCTL_s[<,>]$).

The size of our formulae is the length of the string ³ used to write them down in a sufficiently succinct way, e.g., $|A\alpha U_I \beta|$ is $1 + |\alpha| + |\beta| + |I|$. For *I* of the form $[a_1, b_1[\cup \cdots \cup [a_n, b_n[$, we have $|I| \stackrel{\text{def}}{=} \lceil \log a_1 \rceil + \cdots + \lceil \log b_n \rceil$ (assuming $\log(0) = \log(\omega) = 0$). $ht(\varphi)$ denotes the temporal height of formula φ . As usual, it is the maximal number of nested modalities in φ . Obviously, $ht(\varphi)$ is smaller than the size of φ (even when viewed as a dag).

3 Expressivity

Formally, $TCTL_s$ or $TCTL_c$ do not add expressive power to CTL:

Theorem 3.1. Any closed $TCTL_c$ (or $TCTL_s$) formula is equivalent to a CTL formula.

Proof. With any $TCTL_c$ formula φ , and valuation v, we associate a CTL formula $(\varphi)^v$ s.t. $q, v \models \varphi$ iff $q \models (\varphi)^v$ for any state q of any Kripke structure. Then, if φ has no free clock variables, any $(\varphi)^v$ is a CTL equivalent to φ . The definition of $(\varphi)^v$ is given by the following rewrite rules:

$$\begin{array}{ccc} (\varphi \wedge \psi)^v \stackrel{\text{def}}{=} \varphi^v \wedge \psi^v \\ (\neg \varphi)^v \stackrel{\text{def}}{=} \neg \varphi^v \\ (A)^v \stackrel{\text{def}}{=} A \end{array} \qquad (x \sim k)^v \stackrel{\text{def}}{=} \left\{ \begin{array}{c} \top & \text{if } v(x) \sim k, \\ \bot & \text{otherwise} \end{array} \right. \\ (x & \underline{in} \; \varphi)^v \stackrel{\text{def}}{=} \varphi^{v[x \leftarrow 0]} \end{array}$$

³ We sometimes see a formula as a dag, where identical subformulae are only counted once. Such cases are stated explicitly.

$$(\mathsf{AF}\varphi)^{v} \stackrel{\text{def}}{=} \begin{cases} \mathsf{AF}\varphi^{v} & \text{if } v+1 \equiv_{M_{\varphi}} v, \\ \varphi^{v} \lor \mathsf{AX} \Big[\mathsf{A}(\neg tick) \, \mathsf{U} \left((\neg tick \land \varphi^{v}) \lor (tick \land (\mathsf{AF}\varphi)^{v+1}) \right) \Big] & \text{otherwise} \end{cases}$$

$$(\mathsf{E}\varphi \, \mathsf{U} \, \psi)^{v} \stackrel{\text{def}}{=} \begin{cases} \mathsf{E}\varphi^{v} \, \mathsf{U} \, \psi^{v} & \text{if } v+1 \equiv_{M_{\varphi,\psi}} v, \\ \psi^{v} \lor \Big[\varphi^{v} \land \mathsf{EX} \Big(\mathsf{E}(\varphi^{v} \land \neg tick) \, \mathsf{U} \left((\psi^{v} \land \neg tick) \lor (tick \land (\mathsf{E}\varphi \, \mathsf{U} \, \psi)^{v+1}) \right) \Big) \Big] \\ & \text{otherwise} \end{cases}$$

This gives a well-founded definition for $(_)^v$ since in the right-hand sides either $(_)^v$ is recursively applied over subformulae, or $(_)^{v+1}$ is applied on the same formula (or both). But moving from $(_)^v$ to $(_)^{v+1}$ is only done until $v \equiv_M v+1$, which is bound to eventually happen. Then it is a routine matter to check that the correctness invariant (i.e., " $q, v \models \varphi$ iff $q \models (\varphi)^v$ ") is preserved by these rules.

The translation we just gave is easy to describe but the resulting $(\varphi)^v$ formulae have enormous size. It turns out that this cannot be avoided. Even more, we can say that moving from CTL to $TCTL_s[<]$ to $TCTL_s$ to ... allows writing new formulae that have no succinct equivalent at the previous level.

Theorem 3.2. 1. $TCTL_s[<]$ can be exponentially more succinct than CTL, 2. $TCTL_s[<,>]$ can be exponentially more succinct than $TCTL_s[<]$.

The proof is given by the following lemmas.

Lemma 3.3. Any CTL formula equivalent to $EF_{\leq n} A$ (a log n-sized formula) has temporal height at least n.

Proof. Consider the KS described in Figure 3. One easily shows (by structural induction over φ) that for any *CTL* formula φ , $ht(\varphi) \leq i$ implies $\alpha_i \models \varphi$ iff $\alpha_{i+1} \models \varphi$. On the other hand, $\alpha_j \models \mathsf{EF}_{\leq n}A$ iff j < n. Thus any *CTL* equivalent to $\mathsf{EF}_{\leq n}A$

Fig. 3. $\alpha_n \models \mathsf{EF}_{< n+1} A$ and $\alpha_{n+1} \nvDash \mathsf{EF}_{< n+1} A$

must have temporal height larger than n.

Lemma 3.4. Any $TCTL_{s}[<]$ formula equivalent to $EF_{>n} A$ (a log n-sized formula) has temporal height at least n.

Proof. Consider the KS described in Figure 4. One easily shows (by structural induction over φ) that for any formula φ in $TCTL_s[<]$, $ht(\varphi) \leq i$ implies $\alpha_i \models \varphi$ iff $\alpha_{i+1} \models \varphi$ and $\beta_i \models \varphi$ iff $\beta_{i+1} \models \varphi$. On the other hand, $\alpha_j \models \mathsf{EF}_{>n} A$ iff j > n. Thus any $TCTL_s[<]$ equivalent to $\mathsf{EF}_{>n} A$ must have temporal height larger than n.

Let us mention two (natural) conjectures that would allow separating further fragments:

Fig. 4. $\alpha_n \not\models \mathsf{EF}_{>n} A$ and $\alpha_{n+1} \models \mathsf{EF}_{>n} A$

Conjecture 3.5. 1. $TCTL_s[<,>,=]$ can be exponentially more succinct than $TCTL_s[<,>]$,

2. $TCTL_{c}$ can be exponentially more succinct than $TCTL_{s}$.

We have not yet been able to find the required proofs, which are hard to build. The first point is based on the conjecture that any $TCTL_s[<,>]$ formula equivalent to $\mathsf{EF}_{=k}A$ has temporal height at least k. For the second one, we conjecture that any $TCTL_s$ formula equivalent to $x \text{ in } \mathsf{EF}(A \wedge \mathsf{EF}(B \wedge x = k))$ has size at least k.

We have explained how $TCTL_s$ becomes more and more expressive when we allow subscripts with <, then also with >, then also with =. Subscripts of the form "= k" are the main difference between RTCTL and our proposal. They enhance expressivity and make model checking more complex (see § 4).

Once we have $TCTL_s[<,>,=]$, subscripts with intervals are just a convenient shorthand:

Theorem 3.6. $TCTL_s$ is not more succinct than $TCTL_s[<,>,=]$.

Proof. For I of the form $\bigcup_{i=1...n} [a_i, b_i]$, we denote by I-k the set $\bigcup_{i=1...n} [a_i - k, b_i - k]$ (after the obvious normalization if $k > a_1$).

Let φ be a $TCTL_s$ formula. We build an equivalent $TCTL_s[<,>,=]$ formula $\tilde{\varphi}$ with the following equivalences:

$$E \alpha U_{I} \beta \equiv \bigvee_{i=1...n} E \alpha U_{=a_{i}} (E \alpha U_{

$$A \alpha U_{I} \beta \equiv \begin{cases} A \alpha U_{=a_{1}} (A \alpha U_{I-a_{1}} \beta) & \text{if } a_{1} > 0, \\ \neg E(\neg \beta) U_{$$$$

Correctness is easy to check. The size of $\tilde{\varphi}$, seen as a dag, is linear in the size of φ seen as a dag ⁴.

4 Model checking

For the logics we investigate, the model checking problem is the problem of computing whether $q \models \varphi$ for q a state of a KS S and φ a temporal formula. In

⁴ Viewing formulae as dags is convenient here, and agree with our later use of Theorem 3.6 when we investigate efficient model checking for $TCTL_s$.

this section we analyse the complexity of model checking problems for $TCTL_s$ and $TCTL_c$.

Given a KS S and a formula φ , the complexity of model checking can be evaluated in term of |S| and $|\varphi|$. But more discriminating information can be obtained by also looking at the *program complexity* of model checking (i.e., the complexity when φ is fixed and S, q is the only input) and the *formula complexity* (i.e., when S, q is fixed and φ is the only input).

While $TCTL_s$ model checking can be done efficiently, this is not true for $TCTL_c$ (even when considering a fixed KS).

Theorem 4.1. Let $S = \langle Q, R, l \rangle$ be a KS and φ a $TCTL_s$ formula. There exists a model checking algorithm running in time $O((|Q|^3 + |R|) \times |\varphi|)$. Moreover if φ belongs to $TCTL_s[<,>]$, the algorithm runs in time $O((|Q| + |R|) \times |\varphi|)$.

Proof (Idea). The algorithm extends the classical algorithms for CTL and RTCTL (see [EMSS91]) with procedures dealing with $TCTL_s[<,=,>]$ operators (as seen in Theorem 3.6, formulae with interval subscripts can be decomposed). The most expensive procedure concerns the $\mathsf{EU}_{=}$ case where we compute the transitive closures of relations, hence the (quite naive) $O(|Q|^3 + |R|)$. The $TCTL_s[<,>]$ fragment uses only procedures in $O((|Q| + |R|) \times |\varphi|)$.

Theorem 4.2. The model checking problem for $TCTL_c$ is PSPACE-complete. The formula complexity of $TCTL_c$ model checking is PSPACE-complete.

Proof. To prove this result, it is sufficient to show that $TCTL_c$ model checking is in PSPACE ⁵ and that the formula complexity is PSPACE-hard. The proof of this last point relies on ideas from [AL99]: let P be an instance of QBF (Quantified Boolean Formula, a PSPACE-complete problem). W.l.o.g. Pis some $Q_1p_1 \ldots Q_np_n \varphi$ (with $Q_i \in \{\exists, \forall\}$ and φ a propositional formula over p_1, \ldots, p_n). We reduce P to a model checking problem $S, q \models \Phi$ where S is the simple KS ($\{q\}, \{q \rightarrow q\}, \{l(q) = tick\}$) and Φ is the following $TCTL_c$ formula:

$$t \underline{in} \mathsf{EF}\left[t = 1 \land O_1\left(x_1 \underline{in} \mathsf{EF}\left[t = 2 \land \dots \left(t = i \land O_i(x_i \underline{in} \mathsf{EF}(t = i + 1 \land \dots \mathsf{EF}(t = n + 1 \land \tilde{\varphi}) \dots\right)\right]\right)\right]$$

where O_i is $\mathsf{EF}_{\leq 1}$ (resp. $\mathsf{EG}_{\leq 1}$) if Q_i is \exists (resp. \forall) and $\tilde{\varphi}$ is φ where occurrences of p_i have been replaced by $x_i = n + 1 - i$. Observe that any clock x_i is reset at time *i* or *i* + 1 and depending on this reset time the atomic propositions p_i will be interpreted as true or false after the n+1-th transition. The operator $\mathsf{EF}_{\leq 1}$ (resp. $\mathsf{EG}_{\leq 1}$) allows to quantify existentially (resp. universally) over these two reset times. Clearly Φ is valid iff $S, q \models \Phi$.

In practice, one can easily use any CTL model checker for model checking $TCTL_c$ formulae, and the resulting algorithm runs in time $O(|S| .M^{|Cl|}.|\varphi|)$. For

⁵ This uses standard arguments, see the long version for details.

example, with SMV, one just adds one variable for each formula clock and update them in the obvious way. This is much more practical than an approach based on Theorem 3.1 and the complexity is not too frightening for formulae with |Cl|=1 (only one clock), a fragment already more expressive than $TCTL_s$.

A theoretical view. The following table gives a synthetic summary of complexity measures for model checking CTL, $TCTL_s$ and $TCTL_c$, showing that model checking the full $TCTL_s$ is as tractable as model checking CTL in both arguments. On the other hand, model checking $TCTL_c$ requires polynomial space even for a fixed Kripke structure.

| | CTL | $TCTL_{s}$ | $TCTL_{c}$ |
|------------------------------|--------------------|------------|-----------------|
| Complexity of model checking | P-complete | | PSPACE-complete |
| Formula complexity | LOG | SPACE | PSPACE-complete |
| Program complexity | NLOGSPACE-complete | | |

Filling the table. Model checking $TCTL_s$ is in P as we just saw. P-hardness results from the obvious reading of the circuit-value problem (with proper alternation) as a model checking problem for the EX fragment of CTL. The formula complexity of model checking CTL is LOGSPACE and this result can be easily extended to $TCTL_s$. The program complexity of model checking $TCTL_s$ and $TCTL_c$ is NLOGSPACE-complete since we proved (Theorem 3.1) that these logics can be translated into CTL, for which the NLOGSPACE-complete complexity is given in [KVW98].

Symbolic model checking. When it comes to symbolic model checking (i.e., when S is given under the form of a synchronized product of k structures S_1, \ldots, S_k), CTL model checking becomes PSPACE-complete [KVW98], this is also true for $TCTL_s$ and $TCTL_c$:

Theorem 4.3. The symbolic model checking problem for $TCTL_s$ and $TCTL_c$ is PSPACE-complete.

5 Conclusion

We investigated the expressive power and the complexity of model checking for $TCTL_s$ and $TCTL_c$, two quantitative extensions of CTL along the lines of RTCTL [EMSS91,ET99].

The expressive power must be measured in a framework where, strictly speaking, everything can be translated into CTL.

We showed that $TCTL_s$, while more succinct than RTCTL, still allows an efficient model checking algorithm. By contrast $TCTL_c$, the extension of CTL with freeze quantifiers leads to a complexity blow-up.
