Exercise 1 Family of circuits

Definition 1 A boolean circuit with n inputs is an acyclic graph where the n inputs x_1, \dots, x_n are part of the vertices. The internal vertices are labeled with \wedge , \vee (with 2 incoming edges) or \neg (with 1 incoming edge), with an additional distinguished vertex o that is the output (with no exiting edge). The size $|C|$ of a circuit C is its number of vertices (excluding the input ones). For a word $x \in \{0, 1\}^*$, the notation $C(x)$ refers to the output of the circuit C if the input vertices of C are valued with the bits of x .

Definition 2 For a function $t : \mathbb{N} \rightarrow \mathbb{N}$, a family of circuit of size $t(n)$ is a sequence $(C_n)_{n \in \mathbb{N}}$ such that: C_n is an n -input circuit and $|C_n| \leq t(n)$.

Definition 3 A language $L \subseteq \{0, 1\}^*$ is decided by a family of circuit $(C_n)_{n \in \mathbb{N}}$ if for all $n \in \mathbb{N}$, for all $w \in \{0, 1\}^n$, we have: $C_n(w) = 1 \Leftrightarrow w \in L$.

Definition 4 For a function $t : \mathbb{N} \rightarrow \mathbb{N}$, we define $\text{SIZE}(t) := \{L \subseteq \{0, 1\}^* \mid L \text{ is decided by a family of circuits of size } O(t(n))\}$.

Definition 5

$$\text{P/poly} := \cup_{k \in \mathbb{N}} \text{SIZE}(n^k)$$

1. Show that any language $L \subseteq \{0, 1\}^*$ is in size $\text{SIZE}(n \cdot 2^n)$.
2. Show that for all function $t(n) = 2^{o(n)}$, there exists $L \notin \text{SIZE}(t(n))$.
3. Show that P/poly contains undecidable language.
4. Show that P/poly is not countable.

Solution:

1. Let $L \subseteq \{0, 1\}^*$. For all $n \in \mathbb{N}$, we define $f_n : \{0, 1\}^n \rightarrow \{0, 1\}$ by $f_n(w) = 1 \Leftrightarrow w \in L$, for all $w \in \{0, 1\}^n$. Now, let $n \in \mathbb{N}$. Let us construct C_n with $O(n \cdot 2^n)$ vertices such that $C_n(w) = f_n(w)$ for all $w \in \{0, 1\}^n$. The function f_n can be represented as a two-column table with 2^n entries where each valuation of n variables to either 0 or 1 is associated 0 or 1. This table can be represented as a DNF $\phi = \vee_{1 \leq j \leq k} (\wedge_{1 \leq i \leq n} x_i = w_i^j)$ where $(w^j)_{1 \leq j \leq k}$ (for some $k \leq 2^n$) are the words of $\{0, 1\}^n$ ensuring $f_n(w_i) = 1$. Each clause $(\wedge_{1 \leq i \leq n} x_i = w_i^j)$ can be represented by a circuit with $O(n)$ vertices. As there are at most 2^n of them, the formula ϕ can be represented by circuit of size $O(n \cdot 2^n)$.

2. Let us find an upper bound on the number of circuits $d(n)$ of size $t(n)$. There are at most $t(n)$ internal vertices, each labeled by either \vee , \wedge , or \neg . Furthermore, each vertex has at most two predecessors taken among $n + t(n)$ vertices. Overall, there are at most:

$$d(n) \leq 3^{t(n)} \cdot ((t(n) + n)^2)^{t(n)} = (3 \cdot (t(n) + n)^2)^{t(n)} = 2^{t(n) \log((3 \cdot (t(n) + n)^2))}$$

In addition, there are 2^{2^n} functions from $\{0, 1\}^n \rightarrow \{0, 1\}$. Since $t(n) = 2^{o(n)}$, we have $t(n) \cdot \log((3 \cdot (t(n) + n)^2)) = o(2^n)$. We have $d(n) = 2^{o(2^n)}$. Hence, asymptotically, there is not enough circuits of size $t(n)$ to compute all Boolean functions.

3.

4.

Exercise 2 Some alternation

1. Exhibit a polynomial time alternating algorithm that solves QBF.
2. Let ONE – VAL be the problem of deciding whether a boolean formula is satisfied by exactly one valuation. Show that ONE – VAL $\in \Sigma_2^P$.
3. A boolean formula is minimal if it has no equivalent shorter formula where the length of the formula is the number of symbols it contains. Let MIN – FORMULA be the problem of deciding whether a boolean formula is minimal. Show that MIN – FORMULA $\in \Pi_2^P$.

Solution:

1. qbf(nu, phi):

```

      case(phi):
        - phi: propositional formula
              return yes iff nu stisfies phi
        - phi = exists x, phi'
              (exists) choose i in [0,1]
              qbf(nu[x = i], phi')
        - phi = forall x, phi'
              (forall) choose i in [0,1]
              qbf(nu[x = i], phi')
      
```

Here, the number of alternations is unbounded.

2. OneVal(phi):

```

      (exists) choose a valuation nu
      if (nu satisfies phi)
      then
        (forall) choose a valuation nu'
        if (nu' does not satisfy phi) or (nu = nu')
        then return TRUE
        else return FALSE
      else
        return FALSE
      
```

Here we have one alternation, with first the existential states (exists) and then the universal states (forall).

3. MinFormula(phi) :
 - (forall) choose a formula psi with |psi| < |phi|
 - (exists) choose a valuation nu
 - if nu does not satisfy phi <-> psi
 - then
 - return TRUE
 - else
 - return FALSE

Here we have one alternation, with first the universal states (forall) and then the existential states (exists).

Exercise 3 Collapse of PH

1. Prove that if $\Sigma_k^P = \Sigma_{k+1}^P$ for some $k \geq 0$ then $\text{PH} = \Sigma_k^P$. (Remark that this is implied by $\text{P} = \text{NP}$).
2. Show that if $\Sigma_k^P = \Pi_k^P$ for some k then $\text{PH} = \Sigma_k^P$ (i.e. PH collapses).
3. Show that if $\text{PH} = \text{PSPACE}$ then PH collapses.
4. Do you think there is a polynomial time procedure to convert any QBF formula into a QBF formula with at most 10 variables ?

Solution:

First, note that $\Sigma_k^P = \text{co } \Pi_k^P$ for all $k \geq 0$. In the following, all quantification are made with is polynomial bound on the size of the variables considered.

1. Let us assume that $\Sigma_k^P = \Sigma_{k+1}^P$ for some $k \geq 0$, we prove by induction that $\forall j \geq k, \Sigma_k^P = \Sigma_j^P$, This holds for $j = i$. Now, consider some $j > i$ and assume that $\Sigma_k^P = \dots = \Sigma_{j-1}^P$. Let $L \in \Sigma_j^P$. There exists a language $B \in \text{P}$ ensuring: $x \in L \Leftrightarrow \exists y_1, \forall y_2, \dots, Q_j y_j, (x, y_1, \dots, y_j) \in B$ (with the size of all y_l bounded by $p(|x|)$ for some polynomial function p).

Let $L' = \{(x, y_1) \mid |y_1| \leq p(|x|) \wedge \forall y_2, \dots, Q_j y_j, (x, y_1, y_2, \dots, y_j) \in B\}$. We have $L' \in \Pi_{j-1}^P = \text{co } \Sigma_{j-1}^P = \text{co } \Sigma_k^P = \Pi_k^P$. That is, $x \in L \Leftrightarrow \exists y_1, (x, y_1) \in L'$ with $L' \in \Pi_k^P$. In fact, $L \in \Sigma_{k+1}^P = \Sigma_k^P$ by hypothesis.

2. With the previous question, we just have to prove that $\Sigma_k^P = \Sigma_{k+1}^P$.

Let $L \in \Sigma_{k+1}^P$. As previously, There exists a language $B \in \text{P}$ ensuring: $x \in L \Leftrightarrow \exists y_1, \forall y_2, \dots, Q_{k+1} y_{k+1}, (x, y_1, \dots, y_{k+1}) \in B$.

We define $L' = \{(x, y_1) \mid |y_1| \leq p(|x|) \wedge \forall y_2, \dots, Q_{k+1} y_{k+1}, (x, y_1, y_2, \dots, y_{k+1}) \in B\}$. We have $L' \in \Pi_k^P = \Sigma_k^P$ by hypothesis.

That is, there exists $B' \in \text{P}$ such that $x \in L' \Leftrightarrow \exists y_1, \forall y_2, \dots, Q_k y_k, (x, y_1, \dots, y_k) \in B'$. But then, we have $x \in L \Leftrightarrow \exists y, (x, y) \in L'$. This is equivalent to $x \in L \Leftrightarrow \exists y, \exists y_1, \forall y_2, \dots, Q_k y_k, (x, y, y_1, \dots, y_k) \in B'$. This can be rephrased as $x \in L \Leftrightarrow \exists y', \forall y_2, \dots, Q_k y_k, (x, y', \dots, y_k) \in B'$. It follows that $L \in \Sigma_k^P$.

3. If $\text{PH} = \text{PSPACE}$, then QBF is in Σ_k^P for some k . But QBF is a complete problem for PSPACE, and thus PH. Let there be $B \in \text{PH}$, it can be reduced to $\text{QBF} \in \Sigma_k^P$ in logspace, so $B \in \Sigma_k^P$. That is, $\text{PH} = \Sigma_k^P$.
4. It is unlikely that PH collapses, and the statement would imply the previous question.

Exercise 4 Oracles

Consider a language A . A Turing machine with oracle A is a Turing machine with a special additional read/write tape, called the oracle tape, and three special states: $q_{\text{query}}, q_{\text{yes}}, q_{\text{no}}$. Whenever the machine enters the state q_{query} , with some word w written on the oracle tape, it moves **in one step** to the state q_{yes} or q_{no} depending on whether $w \in A$.

We denote by P^A (resp. NP^A) the class of languages decided in by a deterministic (resp. non-deterministic) Turing machine running in polynomial time with oracle A . Given a complexity class \mathcal{C} , we define $\text{P}^{\mathcal{C}} = \bigcup_{A \in \mathcal{C}} \text{P}^A$ (and similarly for NP).

1. Prove that for any \mathcal{C} -complete language A (for logspace reductions), $\text{P}^{\mathcal{C}} = \text{P}^A$ and $\text{NP}^{\mathcal{C}} = \text{NP}^A$.
2. Show that for any language A , $\text{P}^A = \text{P}^{\bar{A}}$ and $\text{NP}^A = \text{NP}^{\bar{A}}$.
3. Prove that if $\text{NP} = \text{P}^{\text{SAT}}$ then $\text{NP} = \text{coNP}$.
4. Show that there exists a language A such that $\text{P}^A = \text{NP}^A$.¹
5. We define inductively the classes $\text{NP}_0 = \text{P}$ and $\text{NP}_{k+1} = \text{NP}^{\text{NP}^k}$. Show that $\text{NP}_k = \Sigma_k^P$ for all $k \geq 0$.

Solution:

1. We do the proof for NP. Obviously, we have $\text{NP}^{\mathcal{C}} \supseteq \text{NP}^A$. Now, $B \in \text{NP}^{\mathcal{C}}$. There exists a non-deterministic Turing machine running in polynomial time deciding B with an oracle $C \in \mathcal{C}$. We also have a logspace (and hence polynomial time) reduction f such that: $x \in \mathcal{C} \Leftrightarrow f(x) \in A$ since A is hard for \mathcal{C} . We build the non-deterministic Turing machine N' that executes N while replacing a call $u \in C?$ with a call $f(u) \in A?$. The Turing machine N' also runs in polynomial time and decides B with the oracle A . That is, $B \in \text{NP}^A$.
2. We simply have to swap the states q_{yes} and q_{no} in the computation.
3. P^{SAT} is a deterministic class, so it is closed by complementation. Hence, if $\text{NP} = \text{P}^{\text{SAT}}$, we have $\text{coNP} = \text{NP}$.
4. Consider $A = \text{QBF}$. By question 1, we have $\text{P}^{\text{QBF}} = \text{P}^{\text{PSPACE}}$ and $\text{NP}^{\text{QBF}} = \text{NP}^{\text{PSPACE}}$. Furthermore, $\text{NP}^{\text{PSPACE}} \subseteq \text{NPSPACE}$ since one can simulate the calls to the oracle in polynomial space (as there is a polynomial number of calls). Therefore, $\text{NP}^{\text{PSPACE}} \subseteq \text{NPSPACE} \subseteq \text{PSPACE} \subseteq \text{P}^{\text{PSPACE}}$.

¹In fact, there also exists a language B such that $\text{P}^B \neq \text{NP}^B$, which does not prove that $\text{P} \neq \text{NP}$.
