TPM - What is it?

**Trusted Platform Module**

Hardware chip designed to enable commodity computers to achieve **greater levels of security** than is possible in software alone.
TPM - What is it?

**Trusted Platform Module**

Hardware chip designed to enable commodity computers to achieve greater levels of security than is possible in software alone.

- more than 200 millions currently in existence (mostly in laptops)  
  → already used by some applications (e.g. Disk encryption)

- specified by the Trusted Computing Group  
  → more than 700 pages of specification

http://www.trustedcomputinggroup.org
TPM functionality

Secure storage:

- TPM stores keys and other sensitive data in its shielded memory
- A user can store content that is encrypted by keys only available to the TPM.
TPM functionality

Secure storage:
- TPM stores keys and other sensitive data in its shielded memory
- A user can store content that is encrypted by keys only available to the TPM.

Platform authentication:
- Each TPM chip has a unique and secret key
- A platform can obtain keys by which it can authenticate itself reliably.
TPM functionality

Secure storage:
- TPM stores keys and other sensitive data in its shielded memory
- A user can store content that is encrypted by keys only available to the TPM.

Platform authentication:
- Each TPM chip has a unique and secret key
- A platform can obtain keys by which it can authenticate itself reliably.

Platform measurement and reporting:
- TPM contains some internal memory slots called PCRs, and some keys can be locked to a particular PCR value
- PCR values can be modified using some specific command (e.g. command Extend).
TPM - How is it used?

Application programming interface:

- create new keys (e.g. CreateWrapKey), and load them into the device (e.g. LoadKey2);

- manipulate these keys, and the PCRs
  - e.g. UnBind allows one to decrypt a ciphertext using a key that is stored into the TPM and locked to the current PCR value
  - e.g. Quote allows one to obtain a certificate attesting that a key is locked to a particular PCR value
  - e.g. Extend allows one to extend the current value of a PCR with some data $x$, i.e. $p := SHA1(p || x)$.  

S. Delaune (LSV)  Formal analysis of protocols based on TPM  23/06/2010  4 / 34
TPM - How is it used?

Application programming interface:

- create new keys (*e.g.* CreateWrapKey), and load them into the device (*e.g.* LoadKey2);

- manipulate these keys, and the PCRs
  - *e.g.* UnBind allows one to decrypt a ciphertext using a key that is stored into the TPM and locked to the current PCR value
  - *e.g.* Quote allows one to obtain a certificate attesting that a key is locked to a particular PCR value
  - *e.g.* Extend allows one to extend the current value of a PCR with some data \( x \), *i.e.* \( p := \text{SHA1}(p || x) \).

The TPM provides a root of trust for a variety of protocols: *e.g.* Microsoft’s hard drive encryption system “BitLocker”, Direct Anonymous Attestation protocol, …
Several attempts to formally analyse the TPM itself

- using a theorem prover [Lin, 2005];
- using ProVerif, e.g. [Delaune et al., 2010]; or
- in some specific models, e.g. [Gürgens et al., 2007, Coker et al., 2010]
Related Work

Several attempts to formally analyse the TPM itself

Our contributions

Formal analysis of protocols based on TPM registers using an automatic tool
Our contributions

Formal analysis of protocols based on TPM registers using an automatic tool

Our approach:
- we use Horn clauses and rely on the ProVerif tool;
- we solve non-termination issues for the class of $k$-stable clauses; and
- we provide a syntactic criterion to conclude to $k$-stability.
Our contributions

Formal analysis of protocols based on TPM registers using an automatic tool

Our approach:
- we use Horn clauses and rely on the ProVerif tool;
- we solve non-termination issues for the class of $k$-stable clauses; and
- we provide a syntactic criterion to conclude to $k$-stability.

Some case studies:
- a simplified version of the Micosoft BitLocker protocol
- a secure envelope protocol

→ both protocols crucially rely on the use of PCR

[Ables & Ryan, 2010]

TPM key hierarchy

Cryptographic key

Keys are arranged in a tree structure and stored in the TPM memory

Storage Root Key created by a special command

Authdata, PCR

In particular, to each TPM key is associated an authdata value and also some PCR values

- authdata is a password shared between the user process and the TPM
- PCR values constrain the state of the TPM. The TPM will use the key only if certain PCRs currently have certain values.
CertifyKey command

**Goal:** allow a user to obtain a certificate on a key that is stored in the device.
CertifyKey command

**Goal:** allow a user to obtain a certificate on a key that is stored in the device.

**Description:**

<table>
<thead>
<tr>
<th>USER</th>
<th>TPM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>current pcr value: ( pcr )</td>
</tr>
<tr>
<td></td>
<td>key table: ( kh_1 \rightarrow [auth_1, sk_1, pk_1, pcr_1] )</td>
</tr>
</tbody>
</table>
CertifyKey command

**Goal:** allow a user to obtain a certificate on a key that is stored in the device.

**Description:**

USER

| CertifyKey, $kh_1$ |

TPM

| current pcr value: $pcr$
| key table: $kh_1 \rightarrow [auth_1, sk_1, pk_1, pcr_1]$

| $certkey(aik, \langle pk_1, pcr_1 \rangle)$ |
**UnBind command**

**Goal:** allow a user to retrieve the content of an encryption provided that the decryption key is stored in the key table of the TPM.
**Goal:** allow a user to retrieve the content of an encryption provided that the decryption key is stored in the key table of the TPM.

**Description:**

<table>
<thead>
<tr>
<th>USER</th>
<th>TPM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>current pcr value: $pcr_1$</td>
</tr>
<tr>
<td></td>
<td>key table: $kh_1 \rightarrow [auth_1, sk_1, pk_1, pcr_1]$</td>
</tr>
</tbody>
</table>
UnBind command

**Goal:** allow a user to retrieve the content of an encryption provided that the decryption key is stored in the key table of the TPM.

**Description:**

- **USER**
  - UnBind, aenc(pk₁, data), kh₁
  - data

- **TPM**
  - current pcr value: pcr₁
  - key table:
    - kh₁ → [auth₁, sk₁, pk₁, pcr₁]
Extend command

**Goal:** allow a user to update the value stored in one of the platform configuration register (PCR).
Extend command

**Goal:** allow a user to update the value stored in one of the platform configuration register (PCR).

**Description:**

<table>
<thead>
<tr>
<th>USER</th>
<th>TPM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>current pcr value: pcr</td>
</tr>
</tbody>
</table>
Extend command

**Goal:** allow a user to update the value stored in one of the platform configuration register (PCR).

**Description:**

USER

```
Extend, n
```

TPM

```
current pcr value: pcr

h(⟨pcr, n⟩)
```
Outline

1. Overview of the TPM
2. Modelling using Horn clauses
3. Analysing with ProVerif
4. Case studies
An introductory example

**Goal:** Alice has two secrets $s_1$ and $s_2$. First, she interacts with Bob, and then Bob can learn one of the secrets (he chooses) but not both.
An introductory example

**Goal:** Alice has two secrets $s_1$ and $s_2$. First, she interacts with Bob, and then Bob can learn one of the secrets (he chooses) but not both.

**Description:**

1. create and load a key pair $(k_1, pk(k_1))$ locked to $h(u_0, a_1)$ in Bob’s TPM;

2. create and load a key pair $(k_2, pk(k_2))$ locked to $h(u_0, a_2)$ in Bob’s TPM;

→ For sake of simplicity, we assume that the keys are already in Bob’s TPM.
An introductory example

**Goal:** Alice has two secrets $s_1$ and $s_2$. First, she interacts with Bob, and then Bob can learn one of the secrets (he chooses) but not both.

**Description:**

1. create and load a key pair $(k_1, pk(k_1))$ locked to $h(u_0, a_1)$ in Bob’s TPM;
2. create and load a key pair $(k_2, pk(k_2))$ locked to $h(u_0, a_2)$ in Bob’s TPM;
   
   → For sake of simplicity, we assume that the keys are already in Bob’s TPM.
3. Bob provides some certificates to Alice (using `CertifyKey`);
An introductory example

Goal: Alice has two secrets $s_1$ and $s_2$. First, she interacts with Bob, and then Bob can learn one of the secrets (he chooses) but not both.

Description:

1. create and load a key pair $(k_1, pk(k_1))$ locked to $h(u_0, a_1)$ in Bob’s TPM;
2. create and load a key pair $(k_2, pk(k_2))$ locked to $h(u_0, a_2)$ in Bob’s TPM;
   -> For sake of simplicity, we assume that the keys are already in Bob’s TPM.
3. Bob provides some certificates to Alice (using CertifyKey);
4. Alice sends $\text{aenc}(pk(k_1), s_1)$ and $\text{aenc}(pk(k_2), s_2)$ to Bob;
An introductory example

Goal: Alice has two secrets $s_1$ and $s_2$. First, she interacts with Bob, and then Bob can learn one of the secrets (he chooses) but not both.

Description:

1. create and load a key pair $(k_1, pk(k_1))$ locked to $h(u_0, a_1)$ in Bob’s TPM;
2. create and load a key pair $(k_2, pk(k_2))$ locked to $h(u_0, a_2)$ in Bob’s TPM;
   
   For sake of simplicity, we assume that the keys are already in Bob’s TPM.
3. Bob provides some certificates to Alice (using CertifyKey);
4. Alice sends $aenc(pk(k_1), s_1)$ and $aenc(pk(k_2), s_2)$ to Bob;
5. Using Extend and UnBind, Bob can obtain either $s_1$ or $s_2$, but not both.
Modelling the attacker

Predicate \(\text{att}(u, v)\) means that there is a reachable state in which the PCR has value \(u\) and the attacker knows \(v\).

Some rules:

\[
\text{att}(x_p, x) \rightarrow \text{att}(x_p, \text{pk}(x))
\]
\[
\text{att}(x_p, x) \land \text{att}(x_p, y) \rightarrow \text{att}(x_p, \text{aenc}(x, y))
\]
\[
\text{att}(x_p, \text{aenc}(\text{pk}(x), y)) \land \text{att}(x_p, x) \rightarrow \text{att}(x_p, y)
\]

Initial knowledge:

\[
\text{att}(u_0, a_1)
\]
\[
\text{att}(u_0, a_2)
\]
Modelling the key table

Predicate key

\( \text{key}(u, sk, pk, v) \) means that there is a reachable state in which the PCR has value \( u \), and the key table has an entry for the key pair \((sk, pk)\) locked to the PCR value \( v \).
Modelling the key table

Predicate key

key\((u, sk, pk, v)\) means that there is a reachable state in which the PCR has value \(u\), and the key table has an entry for the key pair \((sk, pk)\) locked to the PCR value \(v\).

Some initial facts:

\[
\text{key}(u_0, k_1, pk(k_1), h(u_0, a_1)) \\
\text{key}(u_0, k_2, pk(k_2), h(u_0, a_2))
\]
Modelling the key table

**Predicate key**

key\((u, sk, pk, v)\) means that there is a reachable state in which the PCR has value \(u\), and the key table has an entry for the key pair \((sk, pk)\) locked to the PCR value \(v\).

**Some initial facts:**

\[
\begin{align*}
\text{key}(u_0, k_1, pk(k_1), h(u_0, a_1)) \\
\text{key}(u_0, k_2, pk(k_2), h(u_0, a_2))
\end{align*}
\]

**Remarks:**

- we do not allow keys to be deleted from the memory of the TPM;  
  → we allow an unbounded number of keys to be loaded
- the attacker can not modify directly the key table (only through the API).
Modelling the TPM commands (1/2)

CertifyKey

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow \text{att}(x_p, \text{certkey}(aik, \langle x_{pk}, x_{pcr} \rangle))
\]

UnBind

\[
\text{att}(x_p, \text{aenc}(x_{pk}, x_{data})) \land \text{key}(x_p, x_{sk}, x_{pk}, x_p) \rightarrow \text{att}(x_p, x_{data})
\]
The TPM rule for extending and rebooting the PCR is treated in a particular way. We have a dedicated set of inheritance rules.
The TPM rule for extending and rebooting the PCR is treated in a particular way. We have a dedicated set of inheritance rules.

**Extending:**

\[
\text{att}(x_p, x_v) \land \text{att}(x_p, x) \implies \text{att}(h(x_p, x_v), x)
\]

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \land \text{att}(x_p, x_v) \implies \text{key}(h(x_p, x_v), x_{sk}, x_{pk}, x_{pcr})
\]
The TPM rule for extending and rebooting the PCR is treated in a particular way. We have a dedicated set of inheritance rules.

Extending:

\[
\text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x)
\]

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \land \text{att}(x_p, x_v) \rightarrow \text{key}(h(x_p, x_v), x_{sk}, x_{pk}, x_{pcr})
\]

Rebooting:

\[
\text{att}(x_p, x) \rightarrow \text{att}(u_0, x)
\]

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow \text{key}(u_0, x_{sk}, x_{pk}, x_{pcr}) \text{ (optional)}
\]
Modelling the protocol

Protocol rules:

Considering our introductory example, the role of Alice can be described by the following two rules:

\[
\text{att}(x_p, \text{certkey}(aik, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))
\]

\[
\text{att}(x_p, \text{certkey}(aik, \langle x_{pk}, h(u_0, a_2) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_2))
\]
Modelling the protocol

Protocol rules:

Considering our introductory example, the role of Alice can be described by the following two rules:

\[
\text{att}(x_p, \text{certkey}(\text{aik}, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))
\]

\[
\text{att}(x_p, \text{certkey}(\text{aik}, \langle x_{pk}, h(u_0, a_2) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_2))
\]

Query

Is Bob able to learn both secrets?

\[
Q = \{\text{att}(x, s_1), \text{att}(x, s_2)\}
\]
Going back to our introductory example

The following sequence of ground facts ...

**Initial facts**
- \( \text{key}(u_0, k_1, \text{pk}(k_1), h(u_0, a_1)) \)
- \( \text{att}(u_0, a_1) \)

**CertifyKey**
- \( \text{att}(u_0, \text{certkey}(\text{aik}, \text{pk}(k_1), h(u_0, a_1))) \)

**Alice’s role**
- \( \text{att}(u_0, \text{aenc}(\text{pk}(k_1), s_1)) \)

**Extend**
- \( \text{key}(h(u_0, a_1), k_1, \text{pk}(k_1), h(u_0, a_1)) \)
- \( \text{att}(h(u_0, a_1), \text{aenc}(\text{pk}(k_1), s_1)) \)

**UnBind**
- \( \text{att}(h(u_0, a_1), s_1) \)

... is a valid derivation:
Going back to our introductory example

The following sequence of ground facts ...

- **Initial facts**
  - key\((u_0, k_1, pk(k_1), h(u_0, a_1))\)
  - att\((u_0, a_1)\)

- **CertifyKey**
  - att\((u_0, certkey(aik, pk(k_1), h(u_0, a_1)))\)

- **Alice’s role**
  - att\((u_0, aenc(pk(k_1), s_1))\)

- **Extend**
  - key\((h(u_0, a_1), k_1, pk(k_1), h(u_0, a_1))\)
  - att\((h(u_0, a_1), aenc(pk(k_1), s_1))\)

- **UnBind**
  - att\((h(u_0, a_1), s_1)\)

... is a valid derivation:

**Query**

- \(Q_1 = \{\text{att}(x, s_1)\}\) is satisfiable - with \(\theta_1 = x \mapsto h(u_0, a_1)\).
- \(Q_2 = \{\text{att}(x, s_2)\}\) is satisfiable - with \(\theta_2 = x \mapsto h(u_0, a_2)\).
Outline

1. Overview of the TPM
2. Modelling using Horn clauses
3. Analysing with ProVerif
4. Case studies
The ProVerif tool (B. Blanchet)

Available on line:

http://www.proverif.ens.fr/

**Input:** protocols written in Horn clauses

**Characteristics**

- **unbounded** number of sessions
- primitives given by an **equational theory**
- **security properties:** (strong) **secrecy**, correspondence properties, equivalence properties
- sound but not complete, **termination is not guaranteed**
  → the tool works well in practice
The termination problem seems due to the way PCR is modeled:

\[ \text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x) \]

\[ \text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \land \text{att}(x_p, x_v) \rightarrow \text{key}(h(x_p, x_v), x_{sk}, x_{pk}, x_{pcr}) \]
Termination problem

The termination problem seems due to the way PCR is modeled:

\[ \text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x) \]

\[ \text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \land \text{att}(x_p, x_v) \rightarrow \text{key}(h(x_p, x_v), x_{sk}, x_{pk}, x_{pcr}) \]

Main idea

1. Could we **bound** the length of the PCR, *i.e.* the number of times a PCR may be extended between two resets?
2. If the answer is ’yes’, can we **compute** such a bound?
Notion of $k$-stability

**Definition $k$-stable**

A rule $R$ is *$k$-stable* if for any substitution $\theta$ grounding for $R$, for any PCR value $u = h(u_1, u_2)$ such that $\text{length}_{\text{pcr}}(u) > k$ we have that:

- either $(R\theta)[h(u_1, u_2) \rightarrow u_1] = R(\theta[h(u_1, u_2) \rightarrow u_1])$,
- or $(R\theta)[h(u_1, u_2) \rightarrow u_1]$ is a tautology.
Notion of k-stability

Definition \(k\)-stable

A rule \(R\) is \(k\)-stable if for any substitution \(\theta\) grounding for \(R\), for any PCR value \(u = h(u_1, u_2)\) such that \(\text{length}_{pcr}(u) > k\) we have that:

- either \((R\theta)[h(u_1, u_2) \rightarrow u_1] = R(\theta[h(u_1, u_2) \rightarrow u_1])\),
- or \((R\theta)[h(u_1, u_2) \rightarrow u_1]\) is a tautology.

Examples

- \(\text{att}(x_p, \text{certkey}(\text{aik}, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))\)
- \(\text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x)\)
Notion of k-stability

Definition k-stable

A rule $R$ is $k$-stable if for any substitution $\theta$ grounding for $R$, for any PCR value $u = h(u_1, u_2)$ such that $\text{length}_{\text{pcr}}(u) > k$ we have that:

- either $(R\theta)[h(u_1, u_2) \rightarrow u_1] = R(\theta[h(u_1, u_2) \rightarrow u_1])$,
- or $(R\theta)[h(u_1, u_2) \rightarrow u_1]$ is a tautology.

Examples

- $\text{att}(x_p, \text{certkey}(aik, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))$
- $\text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x)$

Proposition

Let $\mathcal{R}$ be a finite set of rules and $Q$ be a query such that $\mathcal{R}$ and $Q$ are $k$-stable. If $Q$ is satisfiable then there exists a $k$-bounded derivation witnessing this fact.
**Lemma**

Let \( k \geq 0 \) be an integer and \( R = H \rightarrow C \) be a rule such that:

1. for all \( h(v_1, v_2) \in st(R) \), length\(_{pcr}(v_1, v_2) \leq k \);
2. for all \( h(v_1, v_2) \in st(H) \), we have that \( v_1 \notin X \);
3. for all \( h(v_1, v_2) \in st(C) \) such that \( v_1 \in X \), we have that \( C[h(v_1, v_2) \rightarrow v_1] \in H \).

Then, we have that the rule \( R \) is \( k \)-stable.
Lemma

Let $k \geq 0$ be an integer and $R = H \rightarrow C$ be a rule such that:

1. For all $h(v_1, v_2) \in \text{st}(R)$, $\text{length}_{\text{pcr}}(v_1, v_2) \leq k$;
2. For all $h(v_1, v_2) \in \text{st}(H)$, we have that $v_1 \notin \mathcal{X}$;
3. For all $h(v_1, v_2) \in \text{st}(C)$ such that $v_1 \in \mathcal{X}$, we have that $C[h(v_1, v_2) \rightarrow v_1] \in H$.

Then, we have that the rule $R$ is $k$-stable.

Examples

- $\text{att}(x_p, \text{certkey}(\text{aik}, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))$
- $\text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x)$
Syntactic criterion to check $k$-stability

Lemma

Let $k \geq 0$ be an integer and $R = H \rightarrow C$ be a rule such that:

1. for all $h(v_1, v_2) \in st(R)$, $\text{length}_{pcr}(v_1, v_2) \leq k$;
2. for all $h(v_1, v_2) \in st(H)$, we have that $v_1 \notin \mathcal{X}$;
3. for all $h(v_1, v_2) \in st(C)$ such that $v_1 \in \mathcal{X}$, we have that $C[h(v_1, v_2) \rightarrow v_1] \in H$.

Then, we have that the rule $R$ is $k$-stable.

Examples

- $\text{att}(x_p, \text{certkey}(\text{aik}, \langle x_{pk}, h(u_0, a_1) \rangle)) \rightarrow \text{att}(x_p, \text{aenc}(x_{pk}, s_1))$
- $\text{att}(x_p, x_v) \land \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, x_v), x)$

Going back to our running example, it is sufficient to consider 1-bounded derivation when checking satisfiability of a query.
Goal: A set of \( k\)-stable rules can be transformed into another “equivalent” set of rules that is more suitable for analysis with ProVerif.
Our transformation

**Goal:** A set of $k$-stable rules can be transformed into another “equivalent” set of rules that is more suitable for analysis with ProVerif.

**Transformation:** we replace each rule $R$ by the set of rules:

$$\{R[x \mapsto u] \mid x \in X, p(x, t_1, \ldots, t_\ell) \in R, \ u \in U_k\}$$

where $U_k = \{u_0, h(u_0, x_1), \ldots, h(\ldots h(u_0, x_1), \ldots, x_k)\}$. 
Our transformation

**Goal:** A set of $k$-stable rules can be transformed into another “equivalent” set of rules that is more suitable for analysis with ProVerif.

**Transformation:** we replace each rule $R$ by the set of rules:

$$\{ R[x \mapsto u] \mid x \in \mathcal{X}, p(x, t_1, \ldots, t_\ell) \in R, \ u \in U_k \}$$

where $U_k = \{ u_0, h(u_0, x_1), \ldots, h(...h(u_0, x_1), \ldots, x_k) \}$.

This transformation effectively bounds the PCR length of possible PCR values that may appear as the first argument of a predicate.

**Theorem**

If the initial set of rules is $k$-stable, then the initial and transformed set of rules are equivalent w.r.t. satisfiability of queries.
1. Overview of the TPM

2. Modelling using Horn clauses

3. Analysing with ProVerif

4. Case studies
TPM’s commands – We consider the following commands.

- Read
- Quote
- CreateWrapKey
- LoadKey2
- CertifyKey
- UnBind
- Seal
- UnSeal
TPM commands

**TPM’s commands** – We consider the following commands.

- Read
- Quote
- CreateWrapKey
- LoadKey2
- CertifyKey
- UnBind
- Seal
- UnSeal

**Simplifications and/or abstractions**
TPM commands

TPM’s commands – We consider the following commands.

- Read
- Quote
- CreateWrapKey
- LoadKey2
- CertifyKey
- UnBind
- Seal
- UnSeal

Simplifications and/or abstractions

1. we do not consider authdata;
   → this is equivalent to giving all the authdata to the attacker
TPM commands

TPM’s commands – We consider the following commands.
- Read
- Quote
- CreateWrapKey
- LoadKey2
- CertifyKey
- UnBind
- Seal
- UnSeal

Simplifications and/or abstractions

1. We do not consider authdata; this is equivalent to giving all the authdata to the attacker
2. The key AIK (attestation identity key) is initially and permanently loaded in the TPM; In reality, we have to create it (MakeIdentity) and to load it (ActivateIdentity)
TPM commands

TPM’s commands – We consider the following commands.

- Read
- Quote
- CreateWrapKey
- LoadKey2
- CertifyKey
- UnBind
- Seal
- UnSeal

Simplifications and/or abstractions

1. we do not consider authdata;
   → this is equivalent to giving all the authdata to the attacker

2. the key AIK (attestation identity key) is initially and permanently loaded in the TPM;
   → In reality, we have to create it (MakeIdentity) and to load it (ActivateIdentity)

3. we only consider one PCR, instead of 24.
Goal: protect the data that are stored on your disk.

your data are encrypted using VEK, which is in turn encrypted with VMK.
A simplified version of the Bitlocker protocol (1/2)

**Goal:** protect the data that are stored on your disk.
→ your data are encrypted using **VEK**, which is in turn encrypted with **VMK**.

**Description of the set-up phase:**
- A new key pair \((sk, pk)\) is generated and loaded in Alice’s TPM
  → using `CreateWrapKey` and `LoadKey2`;
- **VMK** is encrypted under the key \(pk\) locked to \(h(h(u_0, \text{bios}), \text{loader})\)
  → using `Seal`

\[
\text{seal}(pk, vmk, tpmproof, h(h(u_0, \text{bios}), \text{loader}))
\]
A simplified version of the Bitlocker protocol (1/2)

**Goal:** protect the data that are stored on your disk.

→ your data are encrypted using **VEK**, which is in turn encrypted with **VMK**.

**Description of the set-up phase:**
- A new key pair \((sk, pk)\) is generated and loaded in Alice’s TPM
  → using **CreateWrapKey** and **LoadKey2**;
- **VMK** is encrypted under the key \(pk\) locked to \(h(h(u_0, bios), loader)\)
  → using **Seal**

\[
\text{seal}(pk, vmk, tpmproof, h(h(u_0, bios), loader))
\]

**Description of the retrieval phase:**
- a **trust chain** is built: Pre-BIOS → BIOS → loader
- retrieve **VMK** using **Unseal**
- prevent unauthorised retrievals, by extending “deny” into the PCR
Alice’s role setting up the drive encryption in a trusted state:

\[
\text{key}(x_p, x_{sk}, pk(x_{sk}), \text{nil}) \rightarrow \text{att}(x_p, \text{seal}(pk(x_{sk}), \text{vmk}[x_p], \text{tpmproof}, \text{h}(\text{h}(u_0, \text{bios}), \text{loader})))
\]

PCR reboot rules:

\[
\begin{align*}
\text{att}(x_p, x) &\rightarrow \text{att}(\text{h}(\text{h}(u_0, \text{bios}), \text{loader}), \text{deny}), x) \\
\text{att}(x_p, x) &\rightarrow \text{att}(\text{h}(\text{h}(u_0, \text{bios}), \text{loader}_{\text{rogue}}), x) \\
\text{att}(x_p, x) &\rightarrow \text{att}(\text{h}(u_0, \text{bios}_{\text{rogue}}), x)
\end{align*}
\]

Results of our analysis: \( \text{att}(x_p, \text{vmk}[x]) \)

- the rules are 3-stable
- ProVerif quickly concludes that the protocol is safe (using the set of rules obtained by applying our transformation).
Goal: provide some data (secret) to Bob in such a way that Bob can either access the data or revoke his right to access the data.

→ Now, we consider the fact that the TPM can be rebooted.

Description

1. Sealing the envelope:
**Goal:** provide some data (**secret**) to Bob in such a way that Bob can either access the data or revoke his right to access the data.

Now, we consider the fact that the TPM can be **rebooted**.

**Description**

1. **Sealing the envelope:**

   - Alice
     - create nonce \( n \)
   - Bob’s TPM
     - reboot TPM
     - extend \( (n) \)
   - encrypted session
   - create bind key \((sk, pk(sk))\)
     - locked to \( h(h(u_0, n), \text{obtain}) \)
   - \( pk(sk) \) and certificate
   - \( aenc(pk(sk), \text{secret}) \)
**Goal:** provide some data (secret) to Bob in such a way that Bob can either access the data or revoke his right to access the data.

→ Now, we consider the fact that the TPM can be **rebooted**.

**Description**

1. **Sealing the envelope:**

2. **Opening the envelope:**
   → use **Extend** to extend obtain into the PCR,
   → use **UnBind** to decrypt the ciphertext \( \text{aenc}(pk(sk), secret) \);
Goal: provide some data (secret) to Bob in such a way that Bob can either access the data or revoke his right to access the data.

Now, we consider the fact that the TPM can be rebooted.

Description

1. Sealing the envelope:

2. Opening the envelope:
   - use Extend to extend obtain into the PCR,
   - use UnBind to decrypt the ciphertext $aenc(pk(sk), secret)$;

3. Returning the envelope:
   - use Extend to extend deny into the PCR,
   - use Quote to obtain a signature attesting that the current value of the PCR is $h(h(u_0, n), deny)$. This certificate can be used as a proof that Bob will never have access to secret.
Alice’s role

\[
\text{att}(x_p, x) \rightarrow \text{att}(h(x_p, n[x_p]), x)
\]

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow \text{key}(h(x_p, n[x_p]), x_{sk}, x_{pk}, x_{pcr})
\]

\[
\text{att}(x_p, \text{certkey}(aik, pk(sk), h(h(u_0, n[y]), \text{obtain})))
\rightarrow \text{att}(x_p, \text{aenc}(pk(sk), \text{secret}[y]))
\]
Envelope protocol (2/3)

Alice’s role

\[ \text{att}(x_p, x) \rightarrow \text{att}(h(x_p, n[x_p]), x) \]
\[ \text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow \text{key}(h(x_p, n[x_p]), x_{sk}, x_{pk}, x_{pcr}) \]
\[ \text{att}(x_p, \text{certkey}(aik, \text{pk}(sk), h(h(u_0, n[y]), \text{obtain}))) \rightarrow \text{att}(x_p, \text{aenc}(\text{pk}(sk), \text{secret}[y])) \]

Query

- \[ \text{att}(x_p, \text{secret}[y]), \text{ and} \]
- \[ \text{att}(x_p, \text{certpcr}(aik, h(h(u_0, n[y]), \text{deny}), x)). \]
Alice’s role

\[ att(x_p, x) \rightarrow att(h(x_p, n[x_p]), x) \]
\[ key(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow key(h(x_p, n[x_p]), x_{sk}, x_{pk}, x_{pcr}) \]
\[ att(x_p, certkey(aik, pk(sk), h(h(u_0, n[y]), obtain))) \rightarrow att(x_p, aenc(pk(sk), secret[y])) \]

Query

- att(x_p, secret[y]), and
- att(x_p, certpcr(aik, h(h(u_0, n[y]), deny), x)).

All the rules are 2-stable and ProVerif terminates on the set of rules obtained after applying our transformation.
Alice’s role

\[
\text{att}(x_p, x) \rightarrow \text{att}(h(x_p, n[x_p]), x)
\]

\[
\text{key}(x_p, x_{sk}, x_{pk}, x_{pcr}) \rightarrow \text{key}(h(x_p, n[x_p]), x_{sk}, x_{pk}, x_{pcr})
\]

\[
\text{att}(x_p, \text{certkey}(aik, \text{pk}(sk), h(h(u_0, n[y]), \text{obtain})))
\rightarrow \text{att}(x_p, \text{aenc}((\text{pk}(sk), \text{secret}[y])))
\]

Query

- att\((x_p, \text{secret}[y])\), and
- att\((x_p, \text{certpcr}(aik, h(h(u_0, n[y]), \text{deny}), x))\).

All the rules are 2-stable and ProVerif terminates on the set of rules obtained after applying our transformation.

\[\rightarrow \text{false attack}\] due to the nonce abstraction.
Add freshness by adding an additional boot parameter to the \texttt{att} and key predicates.

\[
\text{att}(x_b, x_p, x) \rightarrow \text{att}(x_b, h(x_p, n[x_b]), x)
\]

...
→ **Add freshness** by adding an additional boot parameter to the att and key predicates.

\[
\text{att}(x_b, x_p, x) \rightarrow \text{att}(x_b, h(x_p, n[x_b]), x)
\]

...  

**PCR reboot rules:**

\[
\text{att}(x_b, x_p, x) \rightarrow \text{att}(b(x_b, x_p), u_0, x)
\]

\[
\text{key}(x_b, x_p, srk, pk(srk), nil) \rightarrow \text{key}(b(x_b, x_p), u_0, srk, pk(srk), nil)
\]

\[
\text{key}(x_b, x_p, aik, pk(aik), nil) \rightarrow \text{key}(b(x_b, x_p), u_0, aik, pk(aik), nil)
\]
Add freshness by adding an additional boot parameter to the att and key predicates.

\[
\text{att}(x_b, x_p, x) \rightarrow \text{att}(x_b, h(x_p, n[x_b]), x)
\]

PCR reboot rules:

\[
\begin{align*}
\text{att}(x_b, x_p, x) & \rightarrow \text{att}(b(x_b, x_p), u_0, x) \\
\text{key}(x_b, x_p, \text{srk}, \text{pk}(	ext{srk}), \text{nil}) & \rightarrow \text{key}(b(x_b, x_p), u_0, \text{srk}, \text{pk}(	ext{srk}), \text{nil}) \\
\text{key}(x_b, x_p, \text{aik}, \text{pk}(	ext{aik}), \text{nil}) & \rightarrow \text{key}(b(x_b, x_p), u_0, \text{aik}, \text{pk}(	ext{aik}), \text{nil})
\end{align*}
\]

Result of our analysis:

Due to the boot parameter, ProVerif encounters termination problems.

ProVerif confirms that the protocol is secure (around 30 min) for 1 reboot.
Conclusion and Future Work

Formal Horn clauses-based framework for modelling PCR based protocols.

Our method:

1. model everything using Horn clauses;
2. show that the set of clauses needed are $k$-stable, and apply our attack-preserving transformation;
3. launch ProVerif (or another tool) on the resulting set of clauses.

Case studies: Microsoft Bitlocker protocol, the envelope protocol.
Conclusion and Future Work

Formal Horn clauses-based framework for modelling PCR based protocols.

Our method:

1. model everything using Horn clauses;
2. show that the set of clauses needed are $k$-stable, and apply our attack-preserving transformation;
3. launch ProVerif (or another tool) on the resulting set of clauses.

Case studies: Microsoft Bitlocker protocol, the envelope protocol.

Future work:

1. Analyse PCR based protocols in a less abstract way (hmac, authorisation session mechanisms, ...) and relying on a process calculus.
2. Generalise this work to other stateful aspects of the TPM (e.g. monotonic counters, saved contexts), and other stateful APIs (e.g. PKCS#11)
