Models and termination of proof reduction in the \(\lambda\Pi\)-calculus modulo theory

Gilles Dowek\(^*\)

Abstract

We define a notion of model for the \(\lambda\Pi\)-calculus modulo theory and prove a soundness theorem. We then define a notion of super-consistency and prove that proof reduction terminates in the \(\lambda\Pi\)-calculus modulo any super-consistent theory. We prove this way the termination of proof reduction in several theories including Simple type theory and the Calculus of constructions.

1 Introduction

1.1 Models and termination

In Predicate logic, a model is defined by a domain \(\mathcal{M}\), a set \(\mathcal{B}\) of truth values, and an interpretation function, parametrized by a valuation \(\phi\), mapping each term \(t\) to an element \([t]_\phi\) of \(\mathcal{M}\), and each proposition \(A\) to an element \([A]_\phi\) of \(\mathcal{B}\).

Predicate logic can be extended to Deduction modulo theory [11, 12], where a congruence on propositions defining a computational equality, also known as definitional equality in Constructive type theory [17], is added. Proofs of a proposition \(A\) are then considered to also be proofs of any proposition congruent to \(A\). In Deduction modulo theory, like in Predicate logic, a model is defined by a domain \(\mathcal{M}\), a set \(\mathcal{B}\) of truth values, and an interpretation function.

Usually, the set \(\mathcal{B}\) is the two-element set \(\{0, 1\}\), but the notion of model can be extended to a notion of many-valued model, where \(\mathcal{B}\) is an arbitrary Boolean algebra, a Heyting algebra, a pre-Boolean algebra [5], or a pre-Heyting algebra [9]. Boolean algebras permit to introduce intermediate truth values for propositions that are neither provable nor disprovable, Heyting algebras to construct models of constructive logic, and pre-Boolean and pre-Heyting algebras, where the order relation \(\leq\) is replaced by a pre-order relation, to distinguish a notion of weak equivalence: \([A]_\phi \leq [B]_\phi\) and \([B]_\phi \leq [A]_\phi\), for all \(\phi\), from a notion of strong equivalence: \([A]_\phi = [B]_\phi\), for all \(\phi\). In Deduction modulo theory, the first corresponds to the provability of \(A \iff B\) and the second to the congruence.

In a model valued in a Boolean algebra, a Heyting algebra, a pre-Boolean algebra, or a pre-Heyting algebra, a proposition \(A\) is said to be valid when it is weakly equivalent to the proposition \(\top\), that is when, for all \(\phi\), \([A]_\phi \geq \top\), and this condition can be rephrased as \([A]_\phi = \top\) in Boolean and Heyting algebras. A congruence \(\equiv\) defined on propositions is said to be valid when, for all \(A\) and \(B\) such that \(A \equiv B\), \(A\) and \(B\) are strongly equivalent, that is, for all \(\phi\), \([A]_\phi = [B]_\phi\). Note that the relation \(\leq\) is used in the definition of the validity of a proposition, but not in the definition of the validity of a congruence.

Proof reduction terminates in Deduction modulo a theory defined by a set of axioms \(T\) and a congruence \(\equiv\), when this theory has a model valued in the pre-Heyting algebra of reducibility candidates [12]. As a consequence, proof reduction terminates if the theory is super-consistent, that is if, for all pre-Heyting algebras \(\mathcal{B}\), it has a model valued in \(\mathcal{B}\) [9]. This theorem permits to completely separate the semantic and the syntactic aspects that are often mixed in the usual proofs of termination of proof reduction. The semantic aspect is in the proof of super-consistency of the considered theory and the syntactic in the universal proof that super-consistency implies termination of proof reduction.

\(^*\)Inria and École normale supérieure de Paris-Saclay, gilles.dowek@ens-paris-saclay.fr
For the termination of proof reduction, the congruence matters, but the axioms do not. Thus, the pre-order relation \( \leq \) does not matter in the algebra of reducibility candidates and it is possible to define it as the trivial pre-order relation such that \( C \leq C' \), for all \( C \) and \( C' \). Such a pre-Heyting algebra is said to be trivial. As the pre-order is trivial, all the conditions defining pre-Heyting algebras, such as \( a \land b \leq a, a \land b \leq b \) are always satisfied in a trivial pre-Heyting algebra, and a trivial pre-Heyting algebra is just a set equipped with arbitrary operations \( \land, \rhd \) ... Thus, in order to prove that proof reduction terminates in Deduction modulo a theory defined by a set of axioms \( T \) and a congruence \( \equiv \), it is sufficient to prove that for all trivial pre-Heyting algebras \( B \), the theory has a model valued in \( B \).

1.2 The \( \lambda \Pi \)-calculus modulo theory

In Predicate logic and in Deduction modulo theory, terms, propositions, and proofs belong to three distinct languages. But, it is more thrive to consider a single language, such as the \( \lambda \Pi \)-calculus modulo theory [8], which is implemented in the \textsc{Dedukti} system [1], or Martin-Löf's Logical Framework [21], and express terms, propositions, and proofs, in this language. For instance, in Predicate logic, \( \theta \) is a term, \( P(0) \Rightarrow P(0) \) is a proposition and \( \lambda \alpha : P(0) \, \alpha \) is a proof of this proposition. In the \( \lambda \Pi \)-calculus modulo theory, all these expressions are terms of the calculus. Only their types differ: \( 0 \) has type \texttt{nat}, \( P(0) \Rightarrow P(0) \) has type \texttt{Type} and \( \lambda \alpha : P(0) \, \alpha \) has type \( P(0) \Rightarrow P(0) \).

Like the \( \lambda \Pi \)-calculus, the \( \lambda \Pi \)-calculus modulo theory is a \( \lambda \)-calculus with dependent types, but, like in Deduction modulo theory, its conversion rule is extended to an arbitrary congruence, typically defined with a confluent and terminating rewrite system. This idea of extending the conversion rule beyond \( \beta \)-reduction is already present in Martin-Löf type theory. It is used, in various ways, in different systems [20, 6, 13, 3].

1.3 From pre-Heyting algebras to \( \Pi \)-algebras

The first goal of this paper is to extend the notion of pre-Heyting algebra to a notion of \( \Pi \)-algebra, adapted to the \( \lambda \Pi \)-calculus modulo theory.

In Predicate logic and in Deduction modulo theory, the propositions are built from atomic propositions with the connectors and quantifiers \( \top, \bot, \land, \lor, \Rightarrow, \forall \), and \( \exists \). Accordingly, the operations of a pre-Heyting algebra are \( \top, \bot, \land, \lor, \Rightarrow, \forall \), and \( \exists \). In the \( \lambda \Pi \)-calculus and in the \( \lambda \Pi \)-calculus modulo theory, the only connector is \( \Pi \). Thus, a \( \Pi \)-algebra mainly has an operation \( \Pi \). As expected, its properties are a mixture of those of the implication and of the universal quantifier of the pre-Heyting algebras.

1.4 Layered models

The second goal of this paper is to extend the usual notion of model to the \( \lambda \Pi \)-calculus modulo theory.

Extending the notion of model to many-sorted predicate logic requires to consider not just one domain \( \mathcal{M} \), but a family of domains \( \{ \mathcal{M}_s \}_{s} \) indexed by the sorts. For instance, in a model of Simple type theory, the family of domains is indexed by simple types. In the \( \lambda \Pi \)-calculus modulo theory, the sorts also are just terms of the calculus. Thus, we shall define a model of the \( \lambda \Pi \)-calculus modulo theory by a family of domains \( \{ \mathcal{M}_s \}_{s} \), indexed by the terms of the calculus and a function \( \llbracket \cdot \rrbracket \) mapping each term \( t \) of type \( A \) and valuation \( \phi \) to an element \( \llbracket t \rrbracket_\phi \) of \( \mathcal{M}_A \).

The functions \( \mathcal{M} \) and \( \llbracket \cdot \rrbracket \) are similar, in the sense that both their domains is the set of terms of the calculus. The goal of the model construction is to define the function \( \llbracket \cdot \rrbracket \) and the function \( \mathcal{M} \) can be seen as a tool helping to define this function. For instance, if \( f \) is a constant of type \( A \to A \), where \( A \) is a term of type \texttt{Type}, and we have the rule

\[
\begin{align*}
f(x) & \to x
\end{align*}
\]

we want to define the interpretation \( \llbracket f \rrbracket \) as the identity function over some set, but to state which, we must first define the function \( \mathcal{M} \) mapping the term \( A \) to a set \( \mathcal{M}_A \), and then define \( \llbracket f \rrbracket \) as the identity function over the set \( \mathcal{M}_A \).
In Predicate logic and in Deduction modulo theory, terms may be typed with sorts, but the sorts themselves have no type. In the λΠ-calculus modulo theory, in contrast, terms have types that have types... This explains that, in some cases, constructing the function \( \mathcal{M} \) itself requires to define first another function \( \mathcal{N} \), that is used as a tool helping to define this function. This can be iterated to a several layer model, where the function \( \llbracket \cdot \rrbracket \) is defined with the help of a function \( \mathcal{M} \), that is defined with the help of a function \( \mathcal{N} \), that is defined with the help... The number of layers depends on the model. Such a layered model has been defined for the Calculus of constructions [23], where three interpretation functions are used. Layered constructions are also common in proofs of termination of proof reduction [14, 18, 4], for instance for Pure Type Systems where sorts are stacked: \( \text{Type}_0 : \text{Type}_1 : \text{Type}_2 : \text{Type}_3 \).

Note that, in this definition of the notion of model, when a term \( t \) has type \( A \), we do not require \( \llbracket t \rrbracket_\phi \) to be an element of \( \llbracket A \rrbracket_\phi \), but of \( \mathcal{M}_A \). This is consistent with the notion of model of many-sorted predicate logic, where we require \( \llbracket t \rrbracket_\phi \) to be an element of \( \mathcal{M}_s \) and where \( \llbracket s \rrbracket_\phi \) is often not even defined.

Valuations must be handled with care in such layered models. In a three layer model, for instance, the definition of \( \llbracket t \rrbracket \) is absolute, the definition of \( \llbracket t \rrbracket_\psi \) is relative to a valuation \( \psi \) mapping each variable of type \( A \) to an element of \( \mathcal{N}_A \), and the definition of \( \llbracket t \rrbracket_\phi \) is relative to a valuation \( \psi \) and to a valuation \( \phi \) mapping each variable of type \( A \) to an element of \( \mathcal{M}_A, \psi \).

1.5 Super-consistency and proof reduction

The third goal of this paper is to use this notion of \( \Pi \)-algebra to define a notion of super-consistency.

We prove that proof reduction, that is \( \beta \)-reduction, terminates in the \( \lambda \Pi \)-calculus modulo any super-consistent theory.

1.6 Examples

As examples, we build models to prove the super-consistency of several theories expressed in the \( \lambda \Pi \)-calculus modulo theory including Simple type theory [11] and the Calculus of constructions [8]. Together with subject reduction and confluence, this termination of proof reduction is a property required to define these theories in the system \textit{Dedukti} [1].

In Section 2, we recall the definition of the \( \lambda \Pi \)-calculus modulo theory and give three examples of theories expressed in this framework. In Section 3, we introduce the notion of \( \Pi \)-algebra and that of model for the \( \lambda \Pi \)-calculus modulo theory and we prove a soundness theorem. In Section 4, we define the notion of super-consistency and prove that the three theories introduced in Section 2 are super-consistent. In Section 5, we prove that proof reduction terminates in the \( \lambda \Pi \)-calculus modulo any super-consistent theory.

2 The \( \lambda \Pi \)-calculus modulo theory

2.1 The \( \lambda \Pi \)-calculus

The syntax of the \( \lambda \Pi \)-calculus is

\[ t = x \mid \text{Type} \mid \text{Kind} \mid \Pi x : t \; t \mid \lambda x : t \; t \mid t \; t \]

and the typing rules are given in Figure 1.

As usual, we write \( A \to B \) for \( \Pi x : A \; B \) when \( x \) does not occur in \( B \). The \( \alpha \)-equivalence relation is defined as usual and terms are identified modulo \( \alpha \)-equivalence. The relation \( \beta \)—one step \( \beta \)-reduction at the root—is defined as usual. If \( r \) is a relation on terms, we write \( \to^1_{\beta} \) for the congruence closure of \( r \), \( \to^+_\beta \) for the transitive closure of \( \to^1_{\beta} \), \( \to_{\refl}^* \) for its reflexive-transitive closure, and \( \equiv \) for its reflexive-symmetric-transitive closure.

If \( \Sigma, \Gamma, \) and \( \Delta \) are contexts, a substitution \( \theta \), binding the variables of \( \Gamma \), is said to have type \( \Gamma \leadsto \Delta \) \( m \Sigma \) if for all \( x : A \) in \( \Gamma \), we have \( \Sigma, \Delta \vdash \theta x : \theta A \). In this case, if \( \Sigma, \Gamma \vdash t : B \), then \( \Sigma, \Delta \vdash \theta t : \theta B \).
Types are preserved by $\beta$-reduction. The $\beta$-reduction relation is confluent and strongly terminating. And each term has a unique type modulo $\beta$-equivalence [16].

A term $t$, well-typed in some context $\Gamma$, is a kind if its type in this context is $\text{Kind}$. For instance, $\text{Type}$ and $\text{nat} \to \text{Type}$ are kinds. It is a type family if its type is a kind. In particular, it is a type if its type is $\text{Type}$. For instance, $\text{nat}$, $\text{array}$, and $(\text{array} \ 0)$ are type families, among which $\text{nat}$ and $(\text{array} \ 0)$ are types. It is an object if its type is a type. For instance, $0$ and $[0]$ are objects.

### 2.2 The $\lambda\Pi$-calculus modulo theory

A rewrite rule is a triple $l \longrightarrow^\Gamma r$ where $\Gamma$ is a context and $l$ and $r$ are $\beta$-irreducible terms. If $l \longrightarrow^\Gamma r$ is a rewrite rule $\theta$ is a substitution binding the variables of $\Gamma$, then we say that the term $\theta l$ reduces to the term $\theta r$.

If $\mathcal{R}$ is a rewrite system, that is a set of rewrite rules, then the congruence generated by $\mathcal{R}$, $\equiv_\mathcal{R}$, is the smallest congruence such that if $t$ reduces to $u$, then $t \equiv_\mathcal{R} u$ and the congruence generated by $\beta$ and $\mathcal{R}$, $\equiv_{\beta, 2}$, is the smallest congruence such that if $t \beta$-reduces to $u$ or $t$ reduces to $u$ then $t \equiv_{\beta, 2} u$.

A rewrite system is said to be well-typed, if the reduction relation it defines verifies the subject reduction property, that is if for all contexts $\Delta$ and for all terms $t$, $u$ and $A$, if $\Delta \vdash t : A$ and $t$ reduces to $u$, then $\Delta \vdash u : A$.

**Definition 2.1 (Theory)** A theory is a pair formed with a context $\Sigma$, well-formed in the $\lambda\Pi$-calculus, and a set of rewrite rules $\mathcal{R}$, well-typed in $\Sigma$ in the $\lambda\Pi$-calculus.

The variables declared in $\Sigma$ are called constants. They replace the sorts, the function symbols, and the axioms of a theory in Predicate logic.

**Definition 2.2 (The $\lambda\Pi$-calculus modulo theory)** The $\lambda\Pi$-calculus modulo $\Sigma, \mathcal{R}$ is the extension of the $\lambda\Pi$-calculus obtained modifying the Declaration rules to replace the condition $x \notin \Sigma, \Gamma$, the Variable rules to replace the condition $x : A \in \Gamma$ by $x : A \in \Sigma, \Gamma$, and the Conversion rules to replace the condition $A \equiv_{\beta, 2} B$ with $A \equiv_{\beta, 2} B$. 

![Diagram](image-url)
In this paper, we assume that the relation $\rightarrow^1_{\beta R}$ is confluent and has the subject reduction property. Confluence and subject reduction are indeed needed to prove that when two well-typed terms $t$ and $u$ are equivalent, $t \equiv_{\beta R} u$, there exists a sequence of well-typed terms $t = t_0, \ldots, t_n = u$, such that for each $i$, either $t_i \rightarrow^1_{\beta R} t_{i+1}$ or $t_i \leftarrow^1_{\beta R} t_{i+1}$. The easiest way to prove the existence of such a sequence is to prove, using confluence, the existence of a term $v$ such that $t \rightarrow^∗_{\beta R} v \leftarrow^∗_{\beta R} u$, and then to prove, using subject reduction, that all the terms of this sequence are well-typed. This property is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction. This methodology is then needed to build models and prove termination of proof reduction.

### 2.3 Examples of theories

Simple type theory can be expressed in Deduction modulo theory [10]. The main idea in this presentation is to distinguish terms of type $\eta \rightarrow o$ from propositions. If $t$ is a term of type $o$, the corresponding proposition is written $\varepsilon(t)$. The term $t$ is a propositional content or a code of the proposition $\varepsilon(t)$. This way, it is not possible to quantify over propositions, but it is possible to quantify over codes of propositions: there is no proposition $$\forall X \ (X \Rightarrow X)$$ but there is a proposition $$\forall x \ (\varepsilon(x) \Rightarrow \varepsilon(x))$$ respecting the syntax of Predicate logic, where the predicate symbol $\varepsilon$ is applied to the variable $x$ to form a proposition.

In this presentation, each simple type is a sort and, for each simple type $A$, there is a quantifier $\forall A$. Thus, the language contains an infinite number of sorts and an infinite number of constants.

This presentation can be adapted to the $\lambda$-calculus modulo theory. To avoid declaring an infinite number of constants for simple types, we can just declare two constants $\iota$ and $o$ of type $\text{Type}$ and use the product of the $\lambda$-calculus modulo theory to represent the simple types $\iota \rightarrow o$, $\iota \rightarrow \iota$, $\iota \rightarrow o \ldots$. We should declare an infinite number of quantifiers $\forall A$, indexed by simple types, but this can be avoided as, in each specific proof, only a finite number of quantifiers occur. This leads to the theory presented in Figure 2.

Another possibility is to add the type $A$ as an extra argument of the quantifier $\forall$. To do so, we need to introduce a type $\text{type}$ for codes of simple types, two constants $\iota$ and $o$, of type $\text{type}$, and not $\text{Type}$, a constant $\text{arrow}$ of type $\iota \rightarrow \text{type} \rightarrow \text{type}$, and a decoding function $\eta$ of type $\eta : \text{type} \rightarrow \text{Type}$. This way, the quantifier $\forall$ can be given the type $\Pi A : \text{type} (((\eta o) \rightarrow (\eta o)) \rightarrow (\eta o))$. This leads to the theory presented in Figure 3.

The Calculus of constructions [7] can also be expressed in the $\lambda$-calculus modulo theory [8] as the theory presented in Figure 4. Note that this presentation slightly differs from that of [8]: the symbol $U_{\text{Type}}$ has been replaced everywhere by $\varepsilon_{\text{Kind}}(\text{Type})$ allowing to drop the rule

$$\varepsilon_{\text{Kind}}(\text{Type}) \rightarrow U_{\text{Type}}$$

Then, to keep the notations similar to those of Simple type theory, we write $\text{type}$ for $U_{\text{Kind}}$, $o$ for $\text{Type}$, $\eta$ for $\varepsilon_{\text{Kind}}$, and $\varepsilon$ for $\varepsilon_{\text{Type}}$. We also write $\Pi_{KK}$ for $\Pi_{(\text{Kind},\text{Kind},\text{Kind})}$, $\Pi_{TT}$ for

Figure 3: Simple type theory with a parametric quantifier

\( \hat{\Pi}(Type, Type, Type) \), \( \hat{\Pi}_{KT} \) for \( \hat{\Pi}(Kind, Type, Type) \), and \( \hat{\Pi}_{TK} \) for \( \hat{\Pi}(Type, Kind, Kind) \). Note finally that the symbol \( \hat{\Pi}_{KT} \) is exactly the parametric universal quantifier of Simple type theory, the symbol \( \hat{\Pi}_{TT} \) is a dependent version of the symbol \( ⇒ \) and \( \hat{\Pi}_{KK} \) a dependent version of the symbol \( \rightarrow \). The symbol \( \hat{\Pi}_{TK} \), in contrast, is new.

These three rewrite systems are confluent because they have no critical pairs [24]. And they have the subject reduction property, because, in each rule, the left-hand side and the right-hand side are well-typed and have the same type.

# 3 Algebras and Models

## 3.1 \( \Pi \)-algebras

The notion of \( \Pi \)-algebra is an adaptation of that of pre-Heyting algebra to the \( \lambda \Pi \)-calculus modulo theory. In this framework, the only connector is \( \Pi \), so in a \( \Pi \)-algebra, there are no operations \( \top \), \( \bot \), \( \land \), \( \lor \), \( ⇒ \), and \( \exists \), like in a pre-Heyting algebra, but a single operation \( \Pi \). As expected, its properties are a mixture of those of the implication and of the universal quantifier of pre-Heyting algebras. Actually, to express these properties, we need two other operations \( \land \) and \( \top \).

**Definition 3.1 (\( \Pi \)-algebra)** A \( \Pi \)-algebra is formed with

- a set \( B \),
- a pre-order relation \( ≤ \) on \( B \),
- an element \( \top \) of \( B \),
- a function \( \land \) from \( B \times B \) to \( B \),
- a subset \( A \) of \( \mathcal{P}^+(B) \), the set of non-empty subsets of \( B \),
- a function \( \Pi \) from \( B \times A \) to \( B \),

such that

- \( \top \) is a maximal element for \( ≤ \), that is for all \( a \) in \( B \), \( a ≤ \top \),
- a \( \land \) \( b \) is a greatest lower bound of \( \{a, b\} \) for \( ≤ \), that is \( a \land b ≤ a \), \( a \land b ≤ b \), and for all \( c \), if \( c ≤ a \) and \( c ≤ b \), then \( c ≤ a \land b \),
- \( a ≤ \Pi(b, S) \) if and only if for all \( c \) in \( S \), \( a \land b ≤ c \).
Note that is the relation \( \leq \) is a pre-order, and not necessarily an order, greatest lower bounds are not necessarily unique, when they exist.

Note also that, from the operation \( \Pi \), we can define an operation \( b \rightarrow c = \Pi(b, \{c\}) \) that is an exponentiation: \( a \leq b \rightarrow c \) if and only if \( a \wedge b \leq c \). We can also define an operation \( A \): for all sets \( S \) in \( A \), \( \mathcal{A}S = \Pi(\top, S) \). And we have \( a \leq \mathcal{A}S \) if and only if for all \( c \) in \( S \), \( a \wedge \top \leq c \). As \( a \leq a \wedge \top \leq a \), we get \( a \leq \mathcal{A}S \) if and only if for all \( c \) in \( S \), \( a \leq c \). Thus \( \mathcal{A}S \) is a greatest lower bound of \( S \).

We have \( a \leq b \rightarrow \mathcal{A}S \) if and only if \( a \wedge b \leq \mathcal{A}S \) if and only if for all \( c \) in \( S \), \( a \wedge b \leq c \) if and only if \( a \leq \Pi(b, S) \). Thus \( \Pi(b, S) \leq b \rightarrow \mathcal{A}S \leq \Pi(b, S) \). But, as the pre-order relation \( \leq \) is not necessarily an order, we do not always have \( \Pi(b, S) = b \rightarrow \mathcal{A}S \).

**Definition 3.2 (Full \( \Pi \)-algebra)** A \( \Pi \)-algebra is full if \( A = \mathcal{P}^+(B) \), that is if \( \Pi \) is total on \( B \times \mathcal{P}^+(B) \).

All the examples of algebras considered in this paper are full. An example of a non-full algebra would be a Lindenbaum-like syntactic algebra.

**Example.** The algebra \( \langle \{0, 1\}, 1, \wedge, \mathcal{P}^+(\{0, 1\}), \Pi \rangle \), where \( \wedge \) and \( \Pi \) are defined by the tables below, is a \( \Pi \)-algebra. Note that, dropping the middle column of the table of \( \Pi \), we get the table of implication and, dropping the first line, that of the universal quantifier.

\[
\begin{array}{c|c|c}
\wedge & 0 & 1 \\
0 & 0 & 0 \\
1 & 0 & 1 \\
\end{array}
\quad
\begin{array}{c|c|c|c}
\Pi & \{0\} & \{0, 1\} & \{1\} \\
0 & 1 & 1 & 1 \\
1 & 0 & 0 & 1 \\
\end{array}
\]

### 3.2 Models valued in a \( \Pi \)-algebra \( B \)

**Definition 3.3 (Model)** A model is a family of interpretation functions \( D^1, ..., D^n \) such that each \( D^i \) maps each term \( t \) and sequence of functions \( \phi_1, ..., \phi_{i-1} \) whose domains contain the free variables \( t \), to some \( D^i_{t,\phi_1,\ldots,\phi_{i-1}} \).

For the last function \( D^n \), we write \( [t]_{\phi_1,\ldots,\phi_{n-1}} \) instead of \( D^i_{t,\phi_1,\ldots,\phi_{n-1}} \). We also often write \( \overline{\phi} \) for a sequence \( \phi_1, ..., \phi_{n-1} \) and, if \( \tau = c_1, ..., c_{n-1} \), we write \( \overline{\phi}, x = \tau \) for the sequence \( (\phi_1, x = c_1), ..., (\phi_{n-1}, x = c_{n-1}) \).

**Definition 3.4 (Model valued in a \( \Pi \)-algebra \( B \))** Let \( B = (B, \top, \wedge, \mathcal{A}, \Pi) \) be a \( \Pi \)-algebra. A model is valued in \( B \) if
\[D^{n-1}_{\text{Kind}, \phi_1, \ldots, \phi_{n-2}} = D^{n-1}_{\text{Type}, \phi_1, \ldots, \phi_{n-2}} = B,\]

\[[\text{Kind}] \phi_1, \ldots, \phi_{n-1} = [\text{Type}] \phi_1, \ldots, \phi_{n-1} = \top,\]

for all \( \phi_1, \ldots, \phi_{n-1} \) whose domains contain the free variables \( \Pi x : C \ D \)

\[\Pi x : C \ D \phi_1, \ldots, \phi_{n-1} = \bar{\Pi}([C]_{\phi_1, \ldots, \phi_{n-1}} \{ [D]_{\phi_1, x = e_1} \ldots, (\phi_{n-1}, x = e_{n-1}) \mid e_1 \in D^{1}_{C, \phi_1, \ldots, \phi_{n-2}} \ldots, e_{n-1} \in D^{n-1}_{C, \phi_1, \ldots, \phi_{n-2}} \})\]

note that this presupposes that both terms are defined, that is that \( \{ [D]_{\phi_1, x = e_1} \ldots, (\phi_{n-1}, x = e_{n-1}) \mid e_1 \in D^{1}_{C, \phi_1, \ldots, \phi_{n-2}} \ldots, e_{n-1} \in D^{n-1}_{C, \phi_1, \ldots, \phi_{n-2}} \} \) is in \( A \).

**Definition 3.5 (Validity)** Let \( \Sigma, R \) be a theory. A model \( M \) valued in some \( \Pi \)-algebra \( B \) is model of the theory \( \Sigma, R \), or the theory is valid in the model, if

- (Well-typedness) for all \( i \geq 2 \), if \( t \) is a term of type \( B \) in some context \( \Gamma \), \( \phi_1 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{1}_{A, \phi_1, \ldots, \phi_{i-2}} \), \( \phi_{i-1} \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{i-1}_{A, \phi_1, \ldots, \phi_{i-2}} \), then \( D^{i}_{\Gamma, \phi_1, \ldots, \phi_{i-1}} = \phi_{i-1} t \)

- (Variables) for all \( i \geq 2 \), if \( \Gamma \) is a context containing a variable \( x : A \), \( \phi_1 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{1}_{A, \phi_1, \ldots, \phi_{i-2}} \), \( \phi_{i-1} \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{i-1}_{A, \phi_1, \ldots, \phi_{i-2}} \), then

\[D^{i}_{\Gamma, \phi_1, \ldots, \phi_{i-1}} = D^{i}_{\Gamma, \phi_1, \ldots, \phi_{i-1}}(\phi_1, y = a_1) \ldots, (\phi_{i-1}, y = a_{i-1})\]

- (Substitution) for all \( i \), if \( t \) is a term of type \( B \) in some context \( \Gamma \), \( y : C \) and \( u \) is a term of type \( C \) in the context \( \Gamma \), \( \phi_1 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{1}_{A, \phi_1, \ldots, \phi_{i-2}} \), \( \phi_{i-1} \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{i-1}_{A, \phi_1, \ldots, \phi_{i-2}} \), then

\[D^{i}_{\Gamma, \phi_1, \ldots, \phi_{i-1}} = D^{i}_{\Gamma, \phi_1, \ldots, \phi_{i-1}}(\phi_1, y = D^{2}_{\phi_1, \phi_1}(u = y) \ldots, (\phi_{i-1}, y = D^{i}_{\phi_1, \phi_1}(u = y))\]

- (Validity of the congruence) for all \( i \), if \( A \) and \( B \) are well-typed in a context \( \Gamma \), \( A \equiv_{\Gamma} B \), \( \phi_1 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{1}_{A, \phi_1, \ldots, \phi_{i-2}} \), \( \phi_{i-1} \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( D^{i-1}_{A, \phi_1, \ldots, \phi_{i-2}} \), then

\[D^{i}_{A, \phi_1, \ldots, \phi_{i-1}} = D^{i}_{B, \phi_1, \ldots, \phi_{i-1}}\]

- (Validity of the axioms) if \( c \) is a constant \( \Sigma \) of type \( A \), then

\[[A] \geq \top\]

Note that the valuations \( \phi_1, \ldots, \phi_n \) only define the interpretation of the variables declared in \( \Gamma \), so the constants of \( \Sigma \) have an absolute interpretation that depends on the model only.

In the examples presented in this paper, we use the cases \( n = 2 \) and \( n = 3 \) only. The general definition then specializes as follows.

**Example.** When \( n = 2 \), a model is given by two functions \( M \) and \( [\cdot] \) such that

- \( M \) is a function mapping each term \( t \) to some \( M_t \), such that \( M_{\text{Kind}} = M_{\text{Type}} = B \), if \( t \) is a term of type \( B \) in a context \( \Gamma, x : C \) and \( u \) is a term of type \( C \) in the context \( \Gamma \), then

\[M_{t/u} = M_t\]

and if \( A \) and \( B \) are terms well typed in some context \( \Gamma \) and \( A \equiv B \), then

\[M_A = M_B\]
• \([t]_\phi\) is a function mapping each term \(t\) and function \(\phi\) whose domain contains the free variables \(t\), to some \([t]_\phi\) such that \([\text{Kind}]_\phi = [\text{Type}]_\psi = \top\),
\[
[\Pi x : C \, D]_\phi = \mathcal{H}([C]_\phi, \{[D]_{\phi,x=c} \mid c \in \mathcal{M}_C\})
\]
if \(t\) is a term of type \(B\) in a context \(\Gamma\) and \(\phi\) maps each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{M}_A\), then \([t]_\phi\) is in \(\mathcal{M}_B\), \([x]_\phi = \phi x\), if \(t\) is a term of type \(B\) in some context \(\Gamma\) and \(y\) is not declared in \(\Gamma\), \(\phi\) is a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{M}_A\), ..., then
\[
[\mathbf{M}]_\phi = [\mathbf{M},y=a]
\]
if \(t\) is a term of type \(B\) in a context \(\Gamma\), \(x : C\), and \(u\) a term of type \(C\) in the context \(\Gamma\), and \(\phi\) a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{M}_A\), then
\[
[\{(u/x)t\}_\phi = [\{(u/x)\phi,x=[u]\}_\phi]
\]
if \(A\) and \(B\) are well typed in some context \(\Gamma\) and \(A \equiv B\), then for all \(\phi\) mapping every \(x : A\) of \(\Gamma\) to an element of \(\mathcal{M}_A\), \([\mathbf{A}]_\phi = [\mathbf{B}]_\phi\), and if \(c\) is a constant of \(\Sigma\) of type \(A\) then \([\mathbf{A}]_\phi \geq \top\).

This generalizes of the usual definition of model for many-sorted predicate logic.

**Remark.** If \(f\) is a constant of type \(A \rightarrow A \rightarrow A\), we can define the function \(\hat{f}\) mapping \(a\) and \(b\) in \(\mathcal{M}_A\) to \([\{f\ \mathbf{x} \ \mathbf{y}\}]_{x=a,y=b}\). Using substitution, we then get
\[
[\{(f \ u)\}_\phi = [\{(f \ x \ y)\phi,x=[t]_\phi,y=[u]_\phi = \hat{f}([t]_\phi,[u]_\phi)]
\]
which is the usual definition of the notion of interpretation function.

**Remark.** The first interpretation function \(\mathcal{M}\) does not depend on any valuation, so it must be very rudimentary. For instance in Definition 4.4 below, for all objects and most types, we have \(\mathcal{M}_t = \{e\}\). Only the types \(o\), \(o \rightarrow o\) are interpreted in a non trivial way. Nevertheless, it is sufficient to support Definition 4.5.

**Example.** When \(n = 3\), a model is given by three functions \(\mathcal{N}\), \(\mathcal{M}\), and \([\ ]\) such that

- \(\mathcal{N}\) is a function mapping each term \(t\) to some \(\mathcal{N}_t\), such that if \(t\) is a term of type \(B\) in some context \(\Gamma\), \(x : C\) and \(u\) a term of type \(C\) in the context \(\Gamma\), then
\[
\mathcal{N}_{(u/x)t} = \mathcal{N}_t
\]
and if \(A\) and \(B\) are well typed in some context \(\Gamma\) and \(A \equiv B\), then \(\mathcal{N}_A = \mathcal{N}_B\),

- \(\mathcal{M}\) is a function mapping each term \(t\) and function \(\psi\) whose domain contains the free variables \(t\), to some \(\mathcal{M}_{t,\psi}\), such that \(\mathcal{M}_{\text{Kind},\psi} = \mathcal{M}_{\text{Type},\psi} = \mathcal{B}\), if \(t\) is a term of type \(B\) in \(\Gamma\) and \(\psi\) is a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{N}_A\), then \(\mathcal{M}_{t,\psi}\) is in \(\mathcal{B}\), \(\mathcal{M}_{t,\psi} = \psi x\), if \(t\) is a term of type \(B\) in some context \(\Gamma\) and \(y\) is not declared in \(\Gamma\), \(\psi\) is a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{N}_A\) then
\[
\mathcal{M}_{t,\psi} = \mathcal{M}_{t,[\psi,y=a]}
\]
if \(t\) is a term of type \(B\) in a context \(\Gamma\), \(x : C\) and \(u\) a term of type \(C\) in the context \(\Gamma\), and \(\psi\) is a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{N}_A\), then
\[
\mathcal{M}_{(u/x)t,\psi} = \mathcal{M}_{t,[\psi,x,\mathcal{M}_u,\psi]}
\]
and if \(A\) and \(B\) are well typed in some context \(\Gamma\) and \(A \equiv B\), and \(\psi\) is a function mapping each variable \(x : A\) of \(\Gamma\) to an element of \(\mathcal{N}_A\), then \(\mathcal{M}_{A,\psi} = \mathcal{M}_{B,\psi}\).

- \([\ ]\) is a function mapping each term \(t\) and functions \(\psi\), \(\phi\) whose domains contain the free variables \(t\), to some \([t]_{\phi,\psi}\), such that
\[
[\text{Kind}]_{\phi,\psi} = [\text{Type}]_{\phi,\psi} = \top
\]
Theorem 3.1 (Soundness) Let \( \phi \) and \( \psi \) be a model, valued in some \( \Pi \)-algebra \( B \), of a theory \( \Sigma, \mathcal{R} \). Then, for all judgments \( x_1 : A_1, \ldots, x_p : A_p \vdash t : B \) derivable in \( \Sigma, \mathcal{R} \), and for all \( \phi = \phi_1, \ldots, \phi_{n-1} \), where \( \phi_1 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{N}_A \), and \( \phi_2 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A, \ldots, \phi_3 \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A, \ldots, \phi_n \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A \), then

\[
[\Pi x : C. D]_{\phi, \psi} = \Pi([C]_{\phi, \psi}, ([D]_{\phi, \psi, x = c_1}, \ldots, \phi, x = c_2) \mid c_1 \in \mathcal{N}_C, c_2 \in \mathcal{M}_C, \psi)
\]

if \( t \) is a term of type \( B \) in \( \Gamma \), \( \psi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{N}_A \), and \( \phi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A, \psi \), then \([t]_{\phi, \psi} = [t]_{\phi, \psi, y = a_1, \ldots, \phi, y = a_2}\)

if \( t \) is a term of type \( B \) in a context \( \Gamma \), \( x : C \) and \( u \) is a term of type \( C \) in the context \( \Gamma \), \( \psi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{N}_A \), and \( \phi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A \), then

\[
[(u/x)t]_{\phi, \psi} = [(u/x)]_{\phi, \psi, x = [u]_{\phi, \psi}}
\]

if \( A \) and \( B \) are well typed in some context \( \Gamma \) and \( A \equiv B \), and \( \psi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{N}_A \), and \( \phi \) is a function mapping each variable \( x : A \) of \( \Gamma \) to an element of \( \mathcal{M}_A \), then \([A]_{\phi, \psi} = [B]_{\phi, \psi}, \) if \( c \) is a constant of \( \Sigma \) of type \( A \) then \([A] \geq \tilde{\top} \).

**Proof.** By induction on the structure of the derivation of \( x_1 : A_1, \ldots, x_p : A_p \vdash t : B \).

- If the last rule is **Sort** or **Product**, then \( B = \text{Type} \) or \( B = \text{Kind} \), \( [B]_{\psi} = \tilde{\top} \) and

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \leq [B]_{\psi}
\]

- If the last rule is **Variable**, with a constant of \( \Sigma \), then \([B]_{\psi} \geq \tilde{\top} \) and

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \leq [B]_{\psi}
\]

- If the last rule is **Variable**, with a variable of \( \Gamma \), then \( B = A_1 \) and

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \leq [B]_{\psi}
\]

- If the last rule is **Abstraction**, then \( B = \Pi x : C. D \) and by induction hypothesis, for all \( \tilde{v} \) in \( D_{C_1} \times D_{C_2} \times \ldots \times D_{C_{n-1}, \phi_1, \ldots, \phi_{n-2}} \), we have

\[
[A_1]_{\psi, x = \tilde{v}} \ldots \tilde{\land} [A_p]_{\psi, x = \tilde{v}} \tilde{\land} [C]_{\psi, x = \tilde{v}} \leq [D]_{\psi, x = \tilde{v}}
\]

thus, by weakening

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \tilde{\land} [C]_{\psi} \leq [D]_{\psi, x = \tilde{v}}
\]

and

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \leq \Pi([C]_{\psi}, ([D]_{\psi, x = \tilde{v}} \mid \tilde{v} \in D_{C_1} \times D_{C_2} \times \ldots \times D_{C_{n-1}, \phi_1, \ldots, \phi_{n-2}}))
\]

that is

\[
[A_1]_{\psi} \ldots \tilde{\land} [A_p]_{\psi} \leq [\Pi x : C. D]_{\psi}
\]
• If the last rule is Application, then we have \( B = (u/x)D \) and by, induction hypothesis
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [C]_\varphi
\]
and
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [\Pi x : C \cdot D]_\varphi
\]
Thus, for all \( \tau \in D_C^1 \times D_{C,\phi_1}^2 \times \cdots \times D_{C,\phi_1,\ldots,\phi_{n-2}}^{n-1} \), we have
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [D]_\tau_{x=\tau}
\]
In particular, for \( \tau = D_{u,\phi_1}^2 \times D_{u,\phi_1,\phi_2}^3 \cdots D_{u,\phi_1,\ldots,\phi_{n-1}}^n \), we get
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [(u/x)D]_\varphi
\]
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [C]_\varphi
\]
As \( [A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [C]_\varphi \), we have
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [C]_\varphi
\]
Hence
\[
[A_1]_\varphi \cdots \varphi \cdot [A_p]_\varphi \leq [B]_\varphi
\]
• If the last rule is Conversion, then we use the fact that the conversion is valid in the model.

**Corollary 3.1** Let \( M \) be a model, valued in some \( \Pi \)-algebra \( B \), of a theory \( \Sigma, R \). Then, for all judgments \( \vdash t : B \) derivable in \( \Sigma, R \), we have \( [B]_\varphi \geq \top \).

**Corollary 3.2** Let \( M \) be a model, valued in the two-element \( \Pi \)-algebra of Example 3.1, of a theory \( \Sigma, R \). Then, for all judgments \( \vdash t : B \), derivable in this theory, we have \( [B]_\varphi = 1 \).

**Corollary 3.3 (Consistency)** Let \( \Sigma, R \) be a theory that has a model, valued in the two-element \( \Pi \)-algebra of Example 3.1. Then, there is no term \( t \) such that the judgment \( P \) : Type \( \vdash t : P \) is derivable in \( \Sigma, \Gamma \). So some types are empty.

## 4 Super-consistency

### 4.1 Super-consistency

We now want to define a notion of super-consistency: a theory is super-consistent if for every \( \Pi \)-algebra, there exists a model of this theory valued in this algebra.

Unfortunately, this constraint is sometimes too strong, as it does not allow to define interpretations as fixed points, for instance if we have a rule
\[
P \rightarrow ((P \Rightarrow Q) \Rightarrow Q)
\]
we want to define the interpretation of \( P \) as the fixed point of the function mapping \( b \) to \( (b \Rightarrow a) \Rightarrow a \), where \( a \) is the interpretation of \( Q \), but this function does not have a fixed point in all \( \Pi \)-algebras.

Thus, we weaken this constraint, requiring the existence of model for complete \( \Pi \)-algebras only. Defining this notion of completeness requires to introduce an order relation \( \sqsubseteq \), that need not be related to the pre-order \( \leq \).

**Definition 4.1 (Ordered, complete \( \Pi \)-algebra)** A \( \Pi \)-algebra is ordered if it is equipped with an order relation \( \sqsubseteq \) such that the operation \( \Pi \) is left anti-monotonic and right monotonic with respect to \( \sqsubseteq \), that is
• if \( a \subseteq b \), then for all \( S \), \( \bar{\Pi}(b, S) \subseteq \bar{\Pi}(a, S) \),

• if \( S \subseteq T \), then for all \( a \), \( \bar{\Pi}(a, S) \subseteq \bar{\Pi}(a, T) \),

where the relation \( \subseteq \) is extended to sets of elements of \( B \) in a trivial way: \( S \subseteq T \) if for all \( a \in S \), there exists \( b \in T \) such that \( a \subseteq b \).

It is complete if every subset of \( B \) has a least upper bound for the relation \( \subseteq \).

**Definition 4.2 (Super-consistency)** A theory \( \Sigma, \mathcal{R} \), is super-consistent if, for every full, ordered and complete \( \Pi \)-algebra \( B \), there exists a model \( M \), valued in \( B \), of \( \Sigma, \mathcal{R} \).

In the remainder of this section, we prove that the three theories presented in Section 2.3 are super-consistent. In these examples, we do not need to use the fixed point theorem, so we shall simply prove that these theories have a model valued in any \( \Pi \)-algebra.

### 4.2 Simple type theory

Let \( B = (B, \tilde{\top}, \tilde{\wedge}, \mathcal{P}^+(B), \bar{\Pi}) \) be a full \( \Pi \)-algebra. We construct a model of Simple type theory, valued in \( B \), in two steps. The first is the construction of the interpretation function \( M \) and the proof of the validity of the congruence for this function. The second is the construction of the interpretation function \( J, K \) and the proof of the validity of the congruence for this function. The key idea in this construction is to take \( M_0 = B \), to interpret \( \varepsilon \) as the identity over \( B \), and \( \Rightarrow \) like \( \rightarrow \) in order to validate the rewrite rule

\[
\varepsilon (\Rightarrow x y) \rightarrow (\varepsilon x) \rightarrow (\varepsilon y)
\]

**Definition 4.3** Let \( S \) and \( T \) be two sets, we write \( F(S,T) \) for the set of functions from \( S \) to \( T \).

### 4.2.1 The interpretation function \( M \)

The first step of the proof is the construction of the interpretation function \( M \).

Let \( \{e\} \) be an arbitrary one-element set such that \( e \) is not an element of \( B \), a function from \( B \) to \( B \)....

**Definition 4.4** The interpretation function \( M \) is defined as follows

- \( M_{Kind} = M_{Type} = B \),
- \( M_{\Pi x : C} D = F(M_C, M_D) \), except if \( M_D = \{e\} \), in which case \( M_{\Pi x : C} D = \{e\} \),
- \( M_t = M_\Rightarrow = M_\forall x = M_\exists = \{e\} \),
- \( M_o = B \),
- \( M_{s} = \{e\} \),
- \( M_{\lambda x : C} t = M_t \),
- \( M_{\rho(t, u)} = M_t \).

We first prove the two following lemmas.

**Lemma 4.1** Let \( t \) be a term, well-typed in a context \( \Gamma \). If \( t \) is an object, then \( M_t = \{e\} \)

**Proof.** By induction on the structure of the term \( t \). The term \( t \) is neither \( \text{Kind} \), \( \text{Type} \), nor \( o \). It is not a product. If it has the form \( \lambda x : C t' \), then \( t' \) is an object. If it has the form \( (t' t'') \), then \( t' \) is an object.
**Lemma 4.2** Let $t$ be a term, well-typed in a context $\Gamma$, $x : A, \Delta$ and $u$ be a term of type $A$ in the context $\Gamma$. If $u$ is an object then

$$M_{(u/x)t} = M_t$$

**Proof.** By induction on the structure of the term $t$. If $t = x$ then, by Lemma 4.1

$$M_{(u/x)t} = M_u = \{e\} = M_t$$

If $t$ is $\text{Kind}$, $\text{Type}$, a constant, or a variable different from $x$, then $x$ does not occur in $t$. If it is a product, an abstraction, or an application, we use the induction hypothesis.

**Lemma 4.3** *(Validity of the congruence)* Let $t$ and $u$ be two well-typed terms in a context $\Gamma$. If $t \equiv_{\beta_R} u$ then

$$M_t = M_u$$

**Proof.** If $t = ((\lambda x : C t') u')$, then $u'$ is an object and by Lemma 4.2

$$M_{((\lambda x : C t') u')} = M_{u'} = M_{(u'/x)t'}$$

Then, as for all $v$, $M_{(e v)} = M_e = \{e\}$, and if $M_D = \{e\}$, then $M_{\Pi x : C D} = \{e\}$, we have

$$M_{(e C)\to(e D)} = \{e\} = M_{(e (C \Rightarrow D))}$$

and

$$M_{\Pi x : C (e (\forall C \phi))} = \{e\} = M_{(e (\forall C \phi))}$$

We prove, by induction on $t$, that if $t \to_{\beta_R} u$ then $M_t = M_u$ and we conclude with a simple induction on the structure of a reduction of $t$ and $u$ to a common term, using confluence and subject reduction.

### 4.2.2 The interpretation function $[\_]$ function

The second step of the proof is the construction of the interpretation function $[\_]$ and the proof of the validity of the congruence for this function.

**Definition 4.5** The interpretation function $[\_]$ is defined as follows

- $[\text{Kind}]_\phi = [\text{Type}]_\phi = \top$,
- $[\Pi x : C D]_\phi = \Pi([C]_\phi, \{[D]_{\phi, x=c} \mid c \in M_C\})$,
- $[\_]_\phi = \bot$,
- $[\_\phi = \bot$,
- $[\Rightarrow]_\phi$ is the function mapping $a$ and $b$ in $B$ to $\Pi(a, \{b\})$,
- $[\forall C]_\phi$ is the function mapping $f$ in $F(M_C, B)$ to $\Pi([C]_\phi, \{(f c) \mid c \in M_C\})$,
- $[\_\phi$ is the identity on $B$,
- $[\_x = \phi x$,
- $[\lambda x : C t]_\phi$ is the function mapping $C$ in $M_C$ to $[t]_{\phi, x=e}$, except if for all $c$ in $C$, $[t]_{\phi, x=c} = e$ in which case $[\lambda x : C t]_\phi = e$,
- $[t u]_\phi = [t]_\phi [u]_\phi$, except if $[t]_\phi = e$, in which case $[t u]_\phi = e$.

Note that in the last case the function $[t]_\phi$ might be undefined at $[u]_\phi$, in which case the interpretation of $(t u)$ would be undefined. The next lemma shows this never happens, when the term $(t u)$ is well-typed.
Lemma 4.4 (Well-typedness) If $\Gamma \vdash t : B$, and $\phi$ is a function mapping variables $x : A$ of $\Gamma$ to elements of $\mathcal{M}_A$, then

$$\llbracket t \rrbracket_\phi \in \mathcal{M}_B$$

Proof. We check each case of the definition of $\llbracket . \rrbracket$.

Lemma 4.5 (Substitution) Let $t$ be a term, well-typed in a context $\Gamma, x : A$ and $u$ be a term of type $A$ in the context $\Gamma$ and $\phi$ be a function mapping each $x : B$ in $\Gamma$ to an element of $\mathcal{M}_B$. We have

$$\llbracket (u/x)t \rrbracket_\phi = \llbracket t \rrbracket_{\phi,x \mapsto [u]_\phi}$$

Proof. By induction on the structure of the term $t$.

Lemma 4.6 (Validity of the axioms)

$$\llbracket \text{Type} \rrbracket_\phi \geq \top$$

$$\llbracket o \rightarrow o \rightarrow o \rrbracket_\phi \geq \top$$

$$\llbracket (A \rightarrow o) \rightarrow o \rrbracket_\phi \geq \top$$

$$\llbracket o \rightarrow \text{Type} \rrbracket_\phi \geq \top$$

Proof. As $\top \land a \leq \top$ we have $\top \leq \Pi(a, \{ \top \})$. The result then follows from $\llbracket \text{Type} \rrbracket_\phi = \llbracket o \rrbracket_\phi = \top$.

Lemma 4.7 (Validity of the congruence) Let $t$ and $u$ be two well-typed terms in a context $\Gamma$, and $\phi$ is a function mapping variables $x : A$ of $\Gamma$ to elements of $\mathcal{M}_A$. If $t \equiv_{\beta R} u$ then

$$\llbracket t \rrbracket_\phi = \llbracket u \rrbracket_\phi$$

Proof. If $t = ((\lambda x : C t') u')$, then if for all $c$ in $\mathcal{M}_C$, we have $\llbracket t' \rrbracket_{\phi,x \mapsto c} = e$, then

$$\llbracket ((\lambda x : C t') u') \rrbracket_\phi = e = \llbracket t' \rrbracket_{\phi,x \mapsto [u']_\phi} = \llbracket (u'/x)t' \rrbracket_\phi$$

Otherwise

$$\llbracket ((\lambda x : C t') u') \rrbracket_\phi = \llbracket t' \rrbracket_{\phi,x \mapsto [u']_\phi} = \llbracket (u'/x)t' \rrbracket_\phi$$

Then

$$\llbracket (\varepsilon \Rightarrow t' u') \rrbracket_\phi = \Pi([t']_\phi, \{ [u']_\phi \}) = \Pi([t']_\phi, \{ [u']_\phi, (\varepsilon u') \}) = \Pi x : (\varepsilon t') (\varepsilon u') \rrbracket_\phi = \llbracket (\varepsilon t') \rightarrow (\varepsilon u') \rrbracket_\phi$$

and

$$\llbracket (\varepsilon (\forall C t')) \rrbracket_\phi = \Pi([C]_\phi, \{ ([t']_\phi c \mid c \in \mathcal{M}_C) \}) = \Pi y : C (\varepsilon (t' y)) \rrbracket_\phi$$

We prove, by induction on $t$, that if $t \rightarrow_{\beta R}^1 u$ then

$$\llbracket t \rrbracket_\phi = \llbracket u \rrbracket_\phi$$

and we conclude with a simple induction on the structure of a reduction of $t$ and $u$ to a common term, using confluence and subject reduction.

We thus get the following theorem.

Theorem 4.1 Simple type theory is super-consistent.
4.3 Simple type theory with a parametric quantifier

In a model of Simple type theory with a parametric quantifier, like in the previous section, we want to take \( M_0 = \mathcal{B} \). But, unlike in the previous section, we do not have \( o : Type \), but \( o : type : Type \). So \( o \) is now an object.

In the previous section, we took \( M_1 = \{ e \} \) for all objects. This permitted to define \( M_{(t, u)} \) and \( M_{\lambda x : C \rightarrow} \) as \( M_1 \) and validate \( \beta \)-reduction trivially. But this is not possible anymore in Simple type theory with a parametric quantifier, where \( M_0 = \mathcal{B} \) and \( M_{\, \text{arrow}(o, o)} = \mathcal{F}(\mathcal{B}, \mathcal{B}) \). So, we cannot define \( M_{\lambda x : Type \ x} \) to be \( M_1 \), but we need to define it as a function. To help to construct this function, we need to construct first another interpretation function \( (N_1) \), and parametrize the definition of \( M_1 \) itself by a function \( \psi \) mapping variables of type \( A \) to elements of \( \mathcal{N}_A \). Thus the model is a three layer model.

Like in the previous section, we want to define \( M_{\Pi x : C \rightarrow D, \psi} \), as the set of functions from \( M_{C, \psi} \) to \( M_{D, \psi'} \). But to define this set \( M_{D, \psi'} \), we need to extend the function \( \psi \), mapping \( x \) to an element of \( \mathcal{N}_C \). To have such an element of \( \mathcal{N}_C \), we need to define \( M_{\Pi x : C \rightarrow D, \psi} \) as the set of functions mapping \( \langle c', c \rangle \) in \( \mathcal{N}_C \times M_{D, \psi} \) to an element of \( M_{D,(\psi,x=c')} \). As a consequence, if \( \psi \) is a function mapping \( x \) of type \( A \) to some element of \( M_A \), we need to define \( \| (t \ u) \|_\psi \) not as \( \| t \|_\psi \ [u]_\psi \) but as \( \| t \|_\psi \langle M_{\pi,\psi}, [u]_\psi \rangle \). As a consequence \([\_\_]\) must be parametrized by both \( \psi \) and \( \phi \).

Let \( \mathcal{B} = \langle B, \top, \tilde{\lambda}, \mathcal{P}^+(B), \Pi \rangle \) be a full II-algebra.

4.3.1 The interpretation function \( \mathcal{N} \)

The first step of the proof is the definition of the interpretation function \( \mathcal{N} \) and the proof of the validity of the congruence for this function.

Let \( \{ e \} \) be an arbitrary one-element set. Let \( \mathcal{U} \) be a set containing \( \mathcal{B} \) and \( \{ e \} \), and closed by function space and Cartesian product, that is such that if \( S \) and \( T \) are in \( \mathcal{U} \) then so are \( S \times T \) and \( \mathcal{F}(S, T) \). Such a set can be constructed, with the replacement scheme, as follows

\[
\mathcal{U}_0 = \{ \mathcal{B}, \{ e \} \}
\]

\[
\mathcal{U}_{n+1} = \mathcal{U}_n \cup \{ S \times T \mid S, T \in \mathcal{U}_n \} \cup \{ \mathcal{F}(S, T) \mid S, T \in \mathcal{U}_n \}
\]

\[
\mathcal{U} = \bigcup_n \mathcal{U}_n
\]

Then, let \( \mathcal{V} \) be the smallest set containing \( \{ e \} \), \( \mathcal{B} \), and \( \mathcal{U} \), and closed by Cartesian product and dependent function space, that is, if \( S \) is in \( \mathcal{V} \) and \( T \) is a family of elements of \( \mathcal{V} \) indexed by \( S \), then the set of functions mapping an element \( s \) of \( S \) to an element of \( T_s \) is an element of \( \mathcal{V} \). As noted in [19], the construction of the set \( \mathcal{V} \), unlike that of \( \mathcal{U} \), requires an inaccessible cardinal. Note that \( \mathcal{U} \) is both an element and a subset of \( \mathcal{V} \).

**Definition 4.6** The interpretation function \( \mathcal{N} \) is defined as follows

- \( \mathcal{N}_{\text{Type}} = \mathcal{N}_{\text{Kind}} = \mathcal{V} \),
- \( \mathcal{N}_{\Pi x : C \rightarrow D} \) is the set \( \mathcal{F}(\mathcal{N}_C, \mathcal{N}_D) \), except if \( \mathcal{N}_D = \{ e \} \), in which case \( \mathcal{N}_{\Pi x : C \rightarrow D} = \{ e \} \),
- \( \mathcal{N}_{\lambda x : C \rightarrow} = \mathcal{U} \),
- \( \mathcal{N}_t = \mathcal{N}_0 = \mathcal{N}_{\text{arrow}} = \mathcal{N}_{\pi} = \mathcal{N}_{\eta} = \mathcal{N}_e = \{ e \} \),
- \( \mathcal{N}_s = \{ e \} \),
- \( \mathcal{N}_{\lambda x : C \rightarrow t} = \mathcal{N}_1 \),
- \( \mathcal{N}_{(t \ u)} = \mathcal{N}_1 \).

We first prove the two following lemmas.
Lemma 4.8 Let \( t \) be a term, well-typed in a context \( \Gamma \). If the term \( t \) is an object, then
\[
N_t = \{ e \}
\]
Proof. By induction on the structure of the term \( t \). The term \( t \) is neither \( \text{Kind} \), \( \text{Type} \), nor \( \text{type} \). It is not a product. If it has the form \( \lambda x : C \ t' \), then \( t' \) is an object. If it has the form \( (t' \ t'') \), then \( t' \) is an object.

Lemma 4.9 Let \( t \) be a term, well-typed in a context \( \Gamma, x : A \) and \( u \) be a term of type \( A \) in the context \( \Gamma \). If \( u \) is an object, then
\[
N_{(u/x)t} = N_t
\]
Proof. By induction on the structure of the term \( t \). If \( t = x \) then, by Lemma 4.8
\[
N_{(u/x)t} = N_u = \{ e \} = N_t
\]
If \( t \) is \( \text{Kind} \), \( \text{Type} \), a constant, or a variable different from \( x \), then \( x \) does not occur in \( t \). If it is a product, an abstraction, or an application, we use the induction hypothesis.

Lemma 4.10 (Validity of the congruence) Let \( t \) and \( u \) be two well-typed terms in a context \( \Gamma \). If \( t \equiv_{\beta \delta \eta} u \) then
\[
N_t = N_u
\]
Proof. If \( t = ((\lambda x : C \ t') \ u') \), then \( u' \) is an object and by Lemma 4.9
\[
N_{((\lambda x : C \ t') \ u')} = N_{u'} = N_{(u'/x)t'}
\]
Then, as for all \( v \), \( N_{(v)} = N_{v} = \{ e \} \) and if \( N_D = \{ e \} \), then \( N_{\Pi_{x : C} D} = \{ e \} \), we have
\[
N_{((\lambda x : C \ t') \ u')} = \{ e \} = N_{((\lambda x : C \ t') \ u')}
\]
As for all \( v \), \( N_{(v)} = N_{v} = \{ e \} \), and if \( N_D = \{ e \} \), then \( N_{\Pi_{x : C} D} = \{ e \} \), we have
\[
N_{(v \ C D)} = \{ e \} = N_{(v \ C D)}
\]
and
\[
N_{(v \ C D)} = \{ e \} = N_{\Pi_{x : C} (v \ C D)}
\]
We prove, by induction on \( t \), that if \( t \rightarrow_{\beta \delta \eta} u \) then \( N_t = N_u \) and we conclude with a simple induction on the structure of a reduction of \( t \) and \( u \) to a common term, using confluence and subject reduction.

4.3.2 The interpretation function \( M \)
The second step of the proof is the definition of the interpretation function \( M \) and the proof of the validity of the congruence for this function.

Definition 4.7 The interpretation function \( M \) is defined as follows
- \( M_{\text{Kind}, \psi} = M_{\text{Type}, \psi} = B \),
- \( M_{\Pi : C \ D, \psi} \) is the set of functions \( f \) mapping \( \{ c' \}, c \) in \( N_{C} \times M_{C, \psi} \) to an element of \( M_{D, \psi} \), except if for all \( c' \) in \( N_{C} \), \( M_{D, \psi} = \{ e \} \), in which case \( M_{\Pi : C \ D, \psi} = \{ e \} \),
- \( M_{\text{Type}, \psi} = B \),
- \( M_{\eta, \psi} \) is the function of \( F(U, V) \) mapping \( S \) to \( S \),
- \( M_{\varepsilon, \psi} \) is the function of \( F(\{ e \}, V) \), mapping \( e \) to \( \{ e \} \),
• $M_{i,\psi} = \{e\}$,
• $M_{a,\psi} = B$,
• $M_{\text{arrow},\psi}$ is the function mapping $S$ and $T$ in $U$ to the set $\mathcal{F}(\{e\} \times S, T)$, except if $T = \{e\}$ in which case it maps $S$ and $T$ to $\{e\}$,
• $M_{\Rightarrow,\psi} = M_{\psi,\psi} = e$,
• $M_{\text{substitution},\psi} = \psi$,
• $M_{\lambda x : C. t,\psi}$ is the function mapping $e$ in $\mathcal{N}_C$ to $M_{t,(\psi,x=e)}$, except if for all $c$ in $\mathcal{N}_C$, $M_{t,(\psi,x=e)} = e$, in which case $M_{\lambda x : C. t,\psi} = e$,
• $M_{t. u,\psi} = M_{t,\psi} \cdot M_{u,\psi}$, except if $M_{t,\psi} = e$ in which case $M_{t. u,\psi} = e$.

Note that in the last case the function $M_{t. u,\psi}$ might be undefined at $M_{u,\psi}$, in which case the interpretation of $(t \cdot u)$ would be undefined. Lemma shows this never happens, when the term $(t \cdot u)$ is well-typed.

**Lemma 4.11** If $\Gamma \vdash C : \text{Type}$, then $\mathcal{N}_C \in \mathcal{V}$

*Proof.* By induction on the structure of the term $C$. As this term has type $\text{Type}$, it is neither $\text{Kind}$ nor $\text{Type}$.

**Lemma 4.12 (Well-typedness)** If $\Gamma \vdash t : B$ and $\psi$ is a function mapping the variables $x : A$ of $\Gamma$ to elements of $\mathcal{N}_A$, then $M_{t,\psi} \in \mathcal{N}_B$

*Proof.* We check each case of the definition of $M$.

**Lemma 4.13 (Substitution)** Let $t$ be a term, well-typed in a context $\Gamma$, $x : A$ and $u$ be a term of type $A$ in the context $\Gamma$ and $\psi$ be a function mapping each $x : B$ in $\Gamma$ to an element of $\mathcal{N}_B$. We have $M_{(u/x)t,\psi} = M_{t,(\psi,x=\cdot M_{u,\psi})}$

*Proof.* By induction on the structure of the term $t$.

**Lemma 4.14 (Validity of the congruence)** Let $t$ and $u$ be two well-typed terms in a context $\Gamma$ and $\psi$ is a function mapping variables $x : A$ of $\Gamma$ to elements of $\mathcal{N}_A$. If $t \equiv_{\beta\eta} u$ then $M_{t,\psi} = M_{u,\psi}$

*Proof.* If $t = ((\lambda x : C. t') u')$, then if for all $c$ in $\mathcal{N}_C$, $M_{t',(\psi,x=e)} = e$, then
\[
M_{((\lambda x : C. t') \cdot u'),\psi} = e = M_{t',(\psi,x=M_{u',\psi})} = M_{(u'/x)t',\psi}
\]

Otherwise
\[
M_{((\lambda x : C. t') \cdot u'),\psi} = M_{t',(\psi,x=M_{u',\psi})} = M_{(u'/x)t',\psi}
\]

The set $M_{((\eta (\text{arrow} C D)),\psi}$ is the set $\mathcal{F}(\{e\} \times M_{C,\psi}, M_{D,\psi})$, except if $M_{D,\psi} = \{e\}$, in which case $M_{((\eta (\text{arrow} C D)),\psi} = \{e\}$. Using weakening, the set $M_{((\eta C)\rightarrow (\eta D)),\psi}$ is this same set. Thus
\[
M_{((\eta (\text{arrow} C D)),\psi} = M_{((\eta C)\rightarrow (\eta D)),\psi}
\]

We have
\[
M_{(e \Rightarrow C D),\psi} = \{e\} = M_{((e C)\rightarrow (e D)),\psi}
\]
and
\[
M_{e \Rightarrow C D),\psi} = \{e\} = M_{\text{substitution,}(e C) (e (D x)),\psi}
\]

We prove, by induction on $t$, that if $t \rightarrow_{\beta\eta} u$ then $M_{t,\psi} = M_{u,\psi}$ and we conclude with a simple induction on the structure of a reduction of $t$ and $u$ to a common term, using confluence and subject reduction.
4.3.3 The interpretation function $[\cdot]$

The last step of the proof is the definition of the interpretation function $[\cdot]$ and the proof of the validity of the congruence for this function.

**Definition 4.8** The interpretation function $[\cdot]$ is defined as follows

- $[\text{Kind}]_{\psi, \phi} = [\text{Type}]_{\psi, \phi} = \top$,
- $[\Pi x : C \ D]_{\psi, \phi} = \tilde{\Pi}(\{C\}_{\psi, \phi}, \{\{D\}_{(\psi, x=c'), (\phi, x=c)} \mid c' \in \mathcal{N}_C, c \in \mathcal{M}_C, \psi\})$,
- $[\text{type}]_{\psi, \phi} = \top$,
- $[\iota]_{\psi, \phi} = \top$,
- $[o]_{\psi, \phi} = \top$,
- $[\text{arrow}]_{\psi, \phi}$ is the function from $U \times B$ and $U \times B$ to $B$ mapping $(S, a)$ and $(T, b)$ to $\tilde{\Pi}(a, \{b\})$,
- $[\Rightarrow]_{\psi, \phi}$ is the function $(e \times B)$ and $(e \times B)$ to $B$ mapping $(e, a)$ and $(e, b)$ to $\tilde{\Pi}(a, \{b\})$,
- $[\forall \psi, \phi]$ is the function mapping $(S, a)$ in $U \times B$, and $(e, g)$ in $(e \times F[(e \times S) \times B])$ to $\tilde{\Pi}(a, \{\{g \in S\} \mid s \in S\})$,
- $[\eta]_{\psi, \phi}$ is the function from $U \times B$ to $B$, mapping $(S, a)$ to $a$,
- $[e]_{\psi, \phi}$ is the function from $(e \times B)$ to $B$, mapping $(e, a)$ to $a$,
- $[x]_{\psi, \phi} = \phi x$,
- $[\lambda x : C \ t]_{\psi, \phi}$ is the function mapping $(\phi', c)$ in $\mathcal{N}_C \times \mathcal{M}_C, \psi$ to $[t]_{(\psi, x=c'), (\phi, x=c)}$, except if for all $(\phi', c)$ in $\mathcal{N}_C \times \mathcal{M}_C, \psi$, $[t]_{(\psi, x=c'), (\phi, x=c)} = e$, in which case $[\lambda x : C \ t]_{\psi, \phi} = e$,
- $[(t \ u)]_{\psi, \phi} = [t]_{\psi, \phi} \langle \mathcal{M}_u, [u]_{\psi, \phi} \rangle$, except if $[t]_{\psi, \phi} = e$, in which case $[(t \ u)]_{\psi, \phi} = e$.

Note that in the last case the function $[t]_{\psi, \phi}$ might be undefined at $[u]_{\psi, \phi}$, in which case the interpretation of $(t \ u)$ would be undefined. The next lemma shows this never happens, when the term $(t \ u)$ is well-typed.

**Lemma 4.15 (Well-typedness)** If $\Gamma \vdash t : B$, $\psi$ is a function mapping variables $x : A$ of $\Gamma$ to elements of $\mathcal{N}_A$, and $\phi$ is a function mapping variables $x : A$ of $\Gamma$ to elements of $\mathcal{M}_A, \psi$, then

$[t]_{\psi, \phi} \in \mathcal{M}_B, \psi$

**Proof.** We check each case of the definition of $[\cdot]$. Let us check, for instance, that if $t = (t_1 \ t_2)$, $t_1$ has type $\Pi x : C \ D$ and $t_2$ has type $C$, hence $(t_1 \ t_2)$ has type $(t_2/x)D$, then $[(t_1 \ t_2)]_{\psi, \phi}$ is in $\mathcal{M}_{(t_2/x)D, \psi}$. We have $\mathcal{M}_{t_2, \psi}$ is in $\mathcal{N}_C$ and, by induction hypothesis, $[t_1]_{\psi, \phi}$ is in $\mathcal{M}_{\Pi x : C \ D, \psi}$, and $[t_2]_{\psi, \phi}$ is in $\mathcal{M}_{C, \psi}$. We have $[(t_1 \ t_2)]_{\psi, \phi} = ([t_1]_{\psi, \phi} \langle \mathcal{M}_{t_2, \psi}, [t_2]_{\psi, \phi} \rangle)$ and, by definition of $\mathcal{M}_{\Pi x : C \ D, \psi}$, this term is in $\mathcal{M}_{D, (\psi, x=\mathcal{M}_{t_2, \psi})}$, that is $\mathcal{M}_{(t_2/x)D, \psi}$.

**Lemma 4.16 (Substitution)** Let $t$ be a term, well-typed in a context $\Gamma, x : A$ and $u$ be a term of type $A$ in the context $\Gamma$, $\psi$ be a function mapping each $x : B$ in $\Gamma$ to an element of $\mathcal{N}_B, \psi$ and $\phi$ be a function mapping each $x : B$ in $\Gamma$ to an element of $\mathcal{M}_B, \psi$. We have

$[u/x]_{\psi, \phi} = [t]_{(\psi, x=\mathcal{M}_u, \psi), (\phi, x=[u]_{\psi, \phi})}$

**Proof.** By induction on the structure of the term $t$. 

18
Lemma 4.17 (Validity of the axioms)
\[
\begin{align*}
\llbracket Type \rrbracket_\phi & \geq \top \\
\llbracket type \rrbracket_\phi & \geq \top \\
\llbracket type \to type \to type \rrbracket_\phi & \geq \top \\
\llbracket type \to Type \rrbracket_\phi & \geq \top \\
\llbracket (\eta o) \to (\eta o) \to (\eta o) \rrbracket_\phi & \geq \top \\
\llbracket \Pi a : type \ ((\eta o) \to (\eta o)) \rrbracket_\phi & \geq \top \\
\llbracket (\eta o) \to Type \rrbracket_\phi & \geq \top
\end{align*}
\]

Proof. As seen in Lemma 4.6, \( \top \leq \Pi(a, \{\top\}) \). The result then follows from \( \llbracket Type \rrbracket_\phi = \llbracket type \rrbracket_\phi = \llbracket (\eta o) \rrbracket_\phi = \top \).

Lemma 4.18 (Validity of the congruence) Let \( t \) and \( u \) be two well-typed terms in a context \( \Gamma, \psi \) is a function mapping variables \( x : A \) of \( \Gamma \) to elements of \( N_A \) and \( \phi \) is a function mapping variables \( x : A \) of \( \Gamma \) to elements of \( \mathcal{M}_{A,\psi} \). If \( t \equiv_R^\beta u \) then
\[
[\llbracket t \rrbracket_{\psi,\phi} = [\llbracket u \rrbracket_{\psi,\phi}]
\]

Proof. If \( t = ((\lambda x : C.t') \ u') \), then if for all \( c' \) in \( \mathcal{N}_C \) and \( c \) in \( \mathcal{M}_{C,\psi} \) we have \( \llbracket t' \rrbracket_{(\psi,x=c'),(\phi,x=c)} = e \) then
\[
\llbracket((\lambda x : C.t') \ u') \rrbracket_{\psi,\phi} = e = \llbracket t' \rrbracket_{(\psi,x=\mathcal{M}_{C',\psi}), (\phi,x=\llbracket u \rrbracket_{\psi,\phi})} = \llbracket (u'/x)t' \rrbracket_{\psi,\phi}
\]
Otherwise
\[
\llbracket((\lambda x : C.t') \ u') \rrbracket_{\psi,\phi} = \llbracket t' \rrbracket_{(\psi,x=\mathcal{M}_{C',\psi}), (\phi,x=\llbracket u \rrbracket_{\psi,\phi})} = \llbracket (u'/x)t' \rrbracket_{\psi,\phi}
\]
We have
\[
\llbracket (\eta (\text{arrow} C D)) \rrbracket_{\psi,\phi} = \Pi((\llbracket C \rrbracket_{\psi,\phi}, \llbracket D \rrbracket_{\psi,\phi})) = \llbracket (\eta C \to (\eta D)) \rrbracket_{\psi,\phi}
\]
\[
\llbracket (\varepsilon (\Rightarrow C D)) \rrbracket_{\psi,\phi} = \Pi((\llbracket C \rrbracket_{\psi,\phi}, \llbracket D \rrbracket_{\psi,\phi})) = \llbracket (\varepsilon C \to (\varepsilon D)) \rrbracket_{\psi,\phi}
\]
\[
\llbracket (\varepsilon (\forall C D)) \rrbracket_{\psi,\phi} = \Pi((\llbracket C \rrbracket_{\psi,\phi}, \llbracket (\llbracket D \rrbracket_{\psi,\phi} (c,c)) \mid c \in \mathcal{M}_{C,\psi}))) = \Pi \Pi ((\eta C) (\varepsilon (D y)))\rrbracket_{\psi,\phi}
\]
We prove, by induction on \( t \), that if \( t \to_\beta u \) then \( \llbracket t \rrbracket_{\psi,\phi} = [\llbracket u \rrbracket_{\psi,\phi} \) and we conclude with a simple induction on the structure of a reduction of \( t \) and \( u \) to a common term, using confluence and subject reduction.

We thus get the following theorem.

Theorem 4.2 Simple type theory with a parametric quantifier is super-consistent.

Remark. The set \( \mathcal{V} \), thus an inaccessible cardinal, are not really needed to prove the super-consistency of Simple type theory with a parametric quantifier if we can adapt the notion of model in such a way that the family \( \mathcal{N} \) is defined for type families only. Then, Lemma 4.12 is proved for objects only. This is sufficient to define \( \mathcal{M}_{A, type, x,\psi} \) as the identity on \( \mathcal{U} \) and, more generally, the function \( \mathcal{M} \). In this case, the class of sets \( \mathcal{M}_{t,\psi} \) would not be a set, which is common in models of many sorted Predicate logic with an infinite number of sorts.

The systematic development of this notion of partial interpretation is left for future work.
4.4 The Calculus of constructions

A very similar proof can be made for the Calculus of constructions.

In the construction of the interpretation functions \( \mathcal{N}, \mathcal{M}, \) and \([ \cdot ]\), we drop the clauses associated to the symbols \( \iota, \Rightarrow, \forall \) and \textit{arrow} and we add the clauses.

- \( \mathcal{N}_{\Pi TT} = \mathcal{N}_{\Pi TK} = \mathcal{N}_{\Pi K} = \{ e \} \)
- \( \mathcal{M}_{\Pi TK} \) is the function mapping \( S \) in \( \mathcal{U} \) and \( h \) in \( \mathcal{F}(\{ e \}, \mathcal{U}) \) to the set \( \mathcal{F}(\{ e \} \times S, (h \_\_e)) \), except if \( (h \_\_e) = \{ e \} \) in which case it maps \( S \) and \( h \) to \( \{ e \} \),
- \( \mathcal{M}_{\Pi TT} = e \),
- \( \mathcal{M}_{\Pi K} = e \),
- \( \mathcal{M}_{\Pi TK} \) is the function mapping \( e \) and \( h \) in \( \mathcal{F}(\{ e \}, \mathcal{U}) \) to the set \( \mathcal{F}(\{ e \} \times \{ e \}, (h \_\_e)) \), except if \( (h \_\_e) = \{ e \} \) in which case it maps \( e \) and \( h \) to \( \{ e \} \),
- \( [\Pi_{KK}]_{\psi, \phi} \) is the function mapping \( (S, a) \) in \( \mathcal{U} \times \mathcal{B}, (f, g) \) in \( \mathcal{F}(\{ e \}, \mathcal{U}) \times \mathcal{F}(\{ e \} \times S, \mathcal{B}) \) to \( \hat{\Pi}(a, \{ (g \_\_e, s) | s \in S \}) \),
- \( [\Pi_{TT}]_{\psi, \phi} \) is the function mapping \( (e, a) \) in \( \{ e \} \times \mathcal{B} \), and \( (e, g) \) in \( \{ e \} \times \mathcal{F}(\{ e \} \times \{ e \}, \mathcal{B}) \) to \( \hat{\Pi}(a, \{ (g \_\_e) \}) \),
- \( [\hat{\Pi}_{TK}]_{\psi, \phi} \) is the function mapping \( (e, a) \) in \( \{ e \} \times \mathcal{B} \), and \( (f, g) \) in \( \mathcal{F}(\{ e \}, \mathcal{U}) \times \mathcal{F}(\{ e \} \times \{ e \}, \mathcal{B}) \) to \( \hat{\Pi}(a, \{ (g \_\_e) \}) \).

The proof of Lemmas 4.8 and 4.9 are similar.

The proof of Lemma 4.10 is similar, except for the case of rewrite rules.

The proof of Lemma 4.11 is similar.

The proof of Lemma 4.12 must be adapted to check the case of the symbols \( \hat{\Pi}_{KK}, \hat{\Pi}_{TT}, \hat{\Pi}_{KT}, \) and \( \hat{\Pi}_{TK} \).

The proof of Lemma 4.13 is similar.

The proof of Lemma 4.14 is similar, except for the case of rewrite rules.

The set \( \mathcal{M}_{(\eta (\Pi_{KK} C D))} \psi \) is the set \( \mathcal{F}(\{ e \} \times \mathcal{M}_{C, \psi}, (\mathcal{M}_{D, \psi} e)) \), except if \( (\mathcal{M}_{D, \psi} e) = \{ e \} \) in which case \( \mathcal{M}_{(\eta (\Pi_{KK} C D))} \psi = \{ e \} \). The set \( \mathcal{M}_{\Pi x:(\eta (C D)) \psi} \) is this same set. Thus

\[
\mathcal{M}_{(\eta (\Pi_{KK} C D))} \psi = \mathcal{M}_{\Pi x:(\eta (C D)) \psi}
\]

We have

\[
\mathcal{M}_{(\varepsilon (\Pi_{TT} C D))} \psi = \mathcal{M}_{\Pi x:(\varepsilon (C D)) \psi}
\]

We have

\[
\mathcal{M}_{(\varepsilon (\Pi_{KT} C D))} \psi = \mathcal{M}_{\Pi x:(\varepsilon (C D)) \psi}
\]

The set \( \mathcal{M}_{(\eta (\Pi_{TK} C D))} \psi \) is the set \( \mathcal{F}(\{ e \} \times \{ e \}, (\mathcal{M}_{D, \psi} e)) \), except if \( (\mathcal{M}_{D, \psi} e) = \{ e \} \) in which case \( \mathcal{M}_{(\eta (\Pi_{TK} C D))} \psi = \{ e \} \). The set \( \mathcal{M}_{\Pi x:(\eta (C D)) \psi} \) is this same set. Thus

\[
\mathcal{M}_{(\eta (\Pi_{TK} C D))} \psi = \mathcal{M}_{\Pi x:(\eta (C D)) \psi}
\]
The proof of Lemma 4.15 must be adapted to check the case of the symbols $\tilde{\Pi}_{KK}$, $\tilde{\Pi}_{TT}$, $\tilde{\Pi}_{KT}$, and $\tilde{\Pi}_{TK}$.

The proof of Lemma 4.16 is similar.

The proof of Lemma 4.18 is similar, except for the case of rewrite rules.

\[ J(\eta(\tilde{\Pi}_{KK} C D)) \phi, \psi = \tilde{\Pi}(J(C) \phi, \psi, \{(J(D) \phi, \psi (e, s)) | s \in M_{C, \psi}\}) = \Pi y : (\eta C) (\eta (D y)) \phi, \psi \]

\[ J(\epsilon(\tilde{\Pi}_{TT} C D)) \phi, \psi = \tilde{\Pi}(J(C) \phi, \psi, \{(\epsilon(D) \phi, \psi (e, e))\}) = \Pi y : (\epsilon C) (\epsilon (D y)) \phi, \psi \]

\[ J(\eta(\tilde{\Pi}_{KT} C D)) \phi, \psi = \tilde{\Pi}(J(C) \phi, \psi, \{(J(D) \phi, \psi (e, e))\}) = \Pi y : (\eta C) (\epsilon (D y)) \phi, \psi \]

\[ J(\eta(\tilde{\Pi}_{TK} C D)) \phi, \psi = \tilde{\Pi}(J(C) \phi, \psi, \{(J(D) \phi, \psi (e, e))\}) = \Pi y : (\eta C) (\epsilon (D y)) \phi, \psi \]

5 Termination of proof reduction

We finally prove that proof reduction terminates in the $\lambda$Π-calculus modulo any super-consistent theory such as Simple type theory without or with a parametric quantifier or the Calculus of constructions.

In Deduction modulo theory, we can define a congruence with non terminating rewrite rules, without affecting the termination of proof reduction. For instance, the rewrite rule

\[ c \rightarrow c \]

does not terminate, but the congruence it defines is the identity and proofs modulo this congruence are just proofs in pure Predicate logic. Thus, proof reduction in Deduction modulo this congruence terminates. So, in the $\lambda$Π-calculus modulo this congruence, the $\beta$-reduction terminates, but the $\beta R$-reduction does not, as the $R$-reduction alone does not terminate. Here, we restrict to prove the termination of $\beta$-reduction, not $\beta R$-reduction. In some cases, like for the three theories presented above, the termination of the $\beta R$-reduction is a simple corollary of the termination of the $\beta$-reduction. In some others, such as the theory defined by the rule

\[ c \rightarrow c \]

it is not.

The main notion used in this proof is that of reducibility candidate introduced by Girard [15]. Our inductive definition, however, follows that of Parigot [22].

5.1 The candidates

Definition 5.1 (Operations on set of terms) The set $\tilde{T}$ is defined as the set of strongly terminating terms.

Let $C$ be a set of terms and $S$ be a set of sets of terms. The set $\tilde{\Pi}(C, S)$ is defined as the set of strongly terminating terms $t$ such that if $t \rightarrow^{*}_{\beta} \lambda x : A t'$ then for all $t''$ in $C$, and for all $D$ in $S$, $(t''/x)t' \in D$.

Definition 5.2 (Candidates) Candidates are inductively defined by the three rules

- the set $\tilde{T}$ of all strongly terminating terms is a candidate,
- if $C$ is a candidate and $S$ is a set of candidates, then $\tilde{\Pi}(C, S)$ is a candidate,
- if $S$ is a non empty set of candidates, then $\bigcap S$ is a candidate.

We write $C$ for the set of candidates.

The algebra $(C, \leq, \tilde{T}, \lambda, P^{+}(C), \tilde{\Pi})$, where $\leq$ is the trivial relation such that $C \leq C'$ always, and $\lambda$ is any function from $C \times C$ to $C$, for instance the constant function equal to $\tilde{T}$, is a full $\Pi$-algebra.

It is ordered by the subset relation and complete for this order.
Lemma 5.1 (Termination) If $C$ is a candidate, then all the elements of $C$ strongly terminate.

Proof. By induction on the construction of $C$.

Lemma 5.2 (Constants and variables) If $C$ is a candidate and $x$ is a constant or a variable, then $x \in C$.

Proof. By induction on the construction of $C$.

Lemma 5.3 (Closure by reduction) If $C$ is a candidate, $t \in C$, and $t \rightarrow^* t'$, then $t' \in C$.

Proof. By induction on the construction of $C$.

Let $t$ be a term of type $A$ and for $n \geq 2$, we apply the induction hypothesis $t \rightarrow^* t'$ to $t$. Thus, $t' \in C$.

Lemma 5.4 Let $C$ be a candidate and $S$ be a set of candidates, $t_1, t_2$, and $u$ be terms such that $t_1 \in \Pi(C, S)$, $t_2 \in C$, and $(t_1 t_2) \rightarrow^* u$. Then, for all $D$ in $S$, $u \in D$.

Proof. By induction on $n_1 + n_2$ where $n_1$ is the maximum length of a reduction sequence issued from $t_1$, and $n_2$ is the maximum length of a reduction sequence issued from $t_2$.

If the reduction is at the root of the term, then $t_1$ has the form $\lambda x : A t'$ and $u = (t_2/x)t'$. By the definition of $\Pi(C, S)$, $u \in D$. Otherwise, the reduction takes place in $t_1$ or in $t_2$, as the candidates as closed by reduction, we apply the induction hypothesis.

Lemma 5.5 (Applications) Let $C$ be a candidate and $S$ be a set of candidates, $t_1$ and $t_2$ such that $t_1 \in \Pi(C, S)$ and $t_2 \in C$, and $D$ be an element of $S$. Then $(t_1 t_2) \in D$.

Proof. By Lemma 5.4, all the one step reducts of $(t_1 t_2)$ are in $D$. To conclude that $(t_1 t_2)$ itself is in $D$, we prove, by induction on the construction of $D$, that if $D$ is a candidate and all the one-step reducts of the term $(t_1 t_2)$ are in $D$, then $(t_1 t_2)$ is in $D$.

- If $D = \top$, then as all the one-step reducts of the term $(t_1 t_2)$ strongly terminate, the term $(t_1 t_2)$ strongly terminates, and $(t_1 t_2) \in D$.

- If $D = \Pi(C, S)$, then as all the one-step reducts of the term $(t_1 t_2)$ strongly terminate, the term $(t_1 t_2)$ strongly terminates. If moreover $(t_1 t_2) \rightarrow^* \lambda x : A v$, then let $(t_1 t_2) = u_1 u_2 \ldots u_n = \lambda x : A v$ be a reduction sequence from $(t_1 t_2)$ to $\lambda x : A v$. As $(t_1 t_2)$ is an application and $\lambda x : A v$ is not, $n \geq 2$. Thus, $(t_1 t_2) \rightarrow^* u_2 \lambda x : A v$. We have $u_2 \in D$ and $u_2 \rightarrow^* \lambda x : A v$, thus for all $w$ in $C$ and $F$ in $S$, $(w/x)v \in F$. Thus, $(t_1 t_2) \in \Pi(C, S) = D$.

- If $D = \bigcap_i D_i$, then for all $i$, all the one step reducts of $(t_1 t_2)$ are in $D_i$, and, by induction hypothesis $(t_1 t_2) \in D_i$. Thus, $(t_1 t_2) \in D$.

5.2 Termination

Consider a super-consistent theory $\Sigma, R$. We want to prove that $\beta$-reduction terminates in the $\lambda\Pi$-calculus modulo this theory.

As usual, we want to associate a candidate $[A]$ to each term $A$ in such a way that if $t$ is a term of type $A$, then $t \in [A]$. In the $\lambda\Pi$-calculus modulo theory, the main difficulty is to assign a candidates to terms in such a way that if $A \equiv B$ then $[A] = [B]$. For instance, if we have the rule $P \rightarrow P \Rightarrow P$.
that permits to type all lambda-terms, including non terminating ones, we should associate, to the term $P$, a candidate $C$ such that $C = C \Rightarrow C$, but there is no such candidate. For super-consistent theories, in contrast, such an assignment exists, as the theory has a model $\mathcal{M}$ valued in the II-algebra $(\mathcal{C}, \leq, \top, \wedge, P)$.

Consider this model.

If a term $t$ has type $B$ in some context $\Gamma$, then $B$ has type $\text{Type}$ in $\Gamma$, $B$ has type $\text{Kind}$ in $\Gamma$, or $B = \text{Kind}$. Thus, $[B]_{\mathcal{C}}$ is an element of $\mathcal{M}_{\text{Type}} = \mathcal{C}$, $[B]_{\mathcal{C}}$ is an element of $\mathcal{M}_{\text{Kind}} = \mathcal{C}$, or $[B]_{\mathcal{C}} = \top$. In all these cases $[B]_{\mathcal{C}}$ is a candidate.

**Lemma 5.6** Let $\Gamma$ be a context, $\bar{\phi} = \phi_1, ..., \phi_{n-1}$ be a sequence of functions such that $\phi_i$ maps $x : A$ of $\Gamma$ to an element of $\mathcal{D}_{A, \phi_1, ..., \phi_{n-1}}$, $\sigma$ be a substitution mapping every $x : A$ of $\Gamma$ to an element of $[A]_{\mathcal{C}}$ and $t$ a term of type $B$ in $\Gamma$. Then $\sigma t \in [B]_{\mathcal{C}}$.

**Proof.** By induction on the structure of the term $t$.

- If $t = \text{Type}$, then $B = \text{Kind}$, $[B]_{\mathcal{C}} = \top$ and $\sigma t = \text{Type} \in [B]_{\mathcal{C}}$.
- If $t = c$ is a constant of $\Delta$, then $\sigma t = c \in [B]_{\mathcal{C}}$, by Lemma 5.2.
- If $t = x$ is a variable of $\Gamma$, then by definition of $\sigma$, $\sigma t \in [B]_{\mathcal{C}}$.
- If $t = \Pi x : C D$, then $B = \text{Type}$ or $B = \text{Kind}$, and $[B]_{\mathcal{C}} = \top$, $\Gamma \vdash C : \text{Type}$ and $\Gamma, x : C \vdash D : \text{Type}$ or $\Gamma, x : C \vdash D : \text{Kind}$, by induction hypothesis $\sigma C \in [\text{Type}]_{\mathcal{C}} = \top$, that is $\sigma C$ strongly terminates and $\sigma D \in [\text{Type}]_{\mathcal{C}} = \top$ or $\sigma D \in [\text{Kind}]_{\mathcal{C}} = \top$, that is $\sigma D$ strongly terminates. Thus, $\sigma (\Pi x : C D) = \Pi x : \sigma C \sigma D$ strongly terminates also and it is an element of $\top = [B]_{\mathcal{C}}$.
- If $t = \lambda x : C u$ where $u$ has type $D$. Then $B = \Pi x : C D$ and $[B]_{\mathcal{C}} = [\Pi x : C D]_{\mathcal{C}} = \tilde{\Pi}([C]_{\mathcal{C}}, \{[D]_{\mathcal{C}, x=\sigma} & \tilde{\sigma} \in D^1_C \times ... \times D^a_{C, \phi_1, ..., \phi_{n-1}} \} \}$ is the set of terms $s$ such that $s$ strongly terminates and if $s$ reduces to $\lambda x : E s_1$ then for all $s'$ in $[C]_{\mathcal{C}}$ and all $s$ in $D^1_C \times ... \times D^a_{C, \phi_1, ..., \phi_{n-1}}$, $(s'/x)s_1$ is an element of $[D]_{\mathcal{C}, x=\sigma}$. We have $\sigma t = \lambda x : \sigma C \sigma u$, consider a reduction sequence issued from this term. This sequence can only reduce the terms $\sigma C$ and $\sigma u$. By induction hypothesis, the term $\sigma C$ is an element of $[\text{Type}]_{\mathcal{C}} = \top$ and the term $\sigma u$ is an element of $[\mathcal{C}]_{\mathcal{C}}$, thus the reduction sequence is finite. Furthermore, every reduce of $\sigma t$ has the form $\lambda x : C' v$ where $C'$ is a reduct of $\sigma C$ and $v$ is a reduct of $\sigma u$. Let $w$ be any term of $[C]_{\mathcal{C}}$, and $\bar{v}$ be any element of $D^1_C \times ... \times D^a_{C, \phi_1, ..., \phi_{n-1}}$, the term $(w/x)v$ can be obtained by reduction from $((w/x)\circ \sigma)u$. By induction hypothesis, the term $((w/x)\circ \sigma)u$ is an element of $[D]_{\mathcal{C}, x=\sigma}$. Hence, by Lemma 5.3 the term $(w/x)v$ is an element of $[D]_{\mathcal{C}, x=\sigma}$. Therefore, the term $\sigma \lambda x u$ is an element of $[B]_{\mathcal{C}}$.
- If the term $t$ has the form $(u_1 u_2)$ then $u_1$ is a term of type $\Pi x : C D$, $u_2$ a term of type $C$ and $B = (u_2/x)D$. We have $\sigma t = (\sigma u_1 \sigma u_2)$, and by induction hypothesis $\sigma u_1 \in [\Pi x : C D]_{\mathcal{C}} = \tilde{\Pi}([C]_{\mathcal{C}}, \{[D]_{\mathcal{C}, x=\sigma} & \tilde{\sigma} \in D^1_C \times ... \times D^a_{C, \phi_1, ..., \phi_{n-1}} \} \}$ and $\sigma u_2 \in [C]_{\mathcal{C}}$. By Lemma 5.5, $(\sigma u_1 \sigma u_2) \in [D]_{\mathcal{C}, x=\sigma} = D^1_{C, \phi_1, ..., \phi_{n-1}} \times ... \times D^a_{C, \phi_1, ..., \phi_{n-1}} = (u_2/x)D]_{\mathcal{C}} = [B]_{\mathcal{C}}$.

**Theorem 5.1** Let $t$ be a term well-typed in a context $\Gamma$. Then $t$ strongly terminates for $\beta$-reduction.

**Proof.** Let $B$ be the type of $t$ in $\Gamma$, let $\bar{\phi} = \phi_1, ..., \phi_n$ be a sequence of functions such that $\phi_i$ maps $x : A$ of $\Gamma$ to an element of $\mathcal{D}_{A, \phi_1, ..., \phi_{n-1}}$, $\sigma$ be the substitution mapping every $x : A$ of $\Gamma$ to itself. Note that, by Lemma 5.2, this variable is an element of $[A]_{\mathcal{C}}$. Then $t = \sigma t \in [B]_{\mathcal{C}}$. Hence it strongly terminates.
5.3 Weak termination of the $\beta R$-reduction

We finally prove the termination of the $\beta R$-reduction for Simple type theory without or with a parametric quantifier and for the Calculus of constructions. The rules $\mathcal{R}$ of Simple type theory are

\[
\varepsilon (\Rightarrow x y) \rightarrow (\varepsilon x) \rightarrow (\varepsilon y)
\]

\[
\varepsilon (\forall A x) \rightarrow \Pi z : A (\varepsilon (x z))
\]

Then, $\mathcal{R}$-reduction can create $\beta$-redices, but only $\beta$-redices of the form $(\lambda x : A t) z$ where $z$ is a variable. Thus, any term can be weakly $\beta R$-reduced by $\beta$-reducing it first, then reducing the $\mathcal{R}$-redices and the trivial created $\beta$-redices. The termination of this second step can be proved by observing that the number of symbols $\Rightarrow$, $\forall A$ and $\lambda$ reduces at each step.

A similar argument applies to Simple type theory with a parametric quantifier and to the Calculus of constructions.

Acknowledgements

The author wants to thank Frédéric Blanqui, Jean-Pierre Jouannaud, and anonymous referees of the previous version of this paper for very helpful remarks on a previous version of this paper. A short version of this paper was presented at the International Colloquium on Automata, Languages and Programming in 2017.
