## Critical systems

- Transport
- Energy
- Medicine
- Communication
- Finance
- Embedded systems
- …
Disastrous software bugs

Mariner 1 probe, 1962

See http://en.wikipedia.org/wiki/Mariner_1

- Destroyed 293 seconds after launch
- Missing hyphen in the data or program? No!
- Overbar missing in the mathematical specification:
  \( \dot{R}_n \): \( n \)th smoothed value of the time derivative of a radius.
  Without the smoothing function indicated by the bar, the program treated normal minor variations of velocity as if they were serious, causing spurious corrections that sent the rocket off course.
Disastrous software bugs

Ariane 5 flight 501, 1996

See http://en.wikipedia.org/wiki/Ariane_5_Flight_501

- Destroyed 37 seconds after launch (cost: 370 millions dollars).
- Data conversion from a 64-bit floating point to 16-bit signed integer value caused a hardware exception (arithmetic overflow).
- Efficiency considerations had led to the disabling of the software handler (in Ada code) for this error trap.
- The fault occurred in the inertial reference system of Ariane 5. The software from Ariane 4 was re-used for Ariane 5 without re-testing.
- On the basis of those calculations the main computer commanded the booster nozzles, and somewhat later the main engine nozzle also, to make a large correction for an attitude deviation that had not occurred.
- The error occurred in a realignment function which was not useful for Ariane 5.
Disastrous software bugs

Spirit Rover (Mars Exploration), 2004

- Ceased communicating on January 21.
- flash memory management anomaly: too many files on the file system
- Resumed to working condition on February 6.
Disastrous software bugs

Other well-known bugs

- Therac-25, at least 3 death by massive overdoses of radiation.
  Race condition in accessing shared resources.

- Electricity blackout, USA and Canada, 2003, 55 millions people.
  Race condition in accessing shared resources.

  Flaw in the division algorithm, discovered by Thomas Nicely.
  See http://en.wikipedia.org/wiki/Pentium_FDIV_bug

- Needham-Schroeder, authentication protocol based on symmetric encryption.
  Published in 1978 by Needham and Schroeder
  Proved correct by Burrows, Abadi and Needham in 1989
  Flaw found by Lowe in 1995 (man in the middle)
  Automatically proved incorrect in 1996.
  See http://en.wikipedia.org/wiki/Needham-Schroeder_protocol

Model Checking

- Purpose 1: automatically finding software or hardware bugs.
- Purpose 2: prove correctness of abstract models.
- Should be applied during design.
- Real systems can be analysed with abstractions.

E.M. Clarke  E.A. Emerson  J. Sifakis

Prix Turing 2007.
Model Checking

3 steps

- Constructing the model $M$ (transition systems)
- Formalizing the specification $\varphi$ (temporal logics)
- Checking whether $M \models \varphi$ (algorithmics)

Main difficulties

- Size of models (combinatorial explosion)
- Expressivity of models or logics
- Decidability and complexity of the model-checking problem
- Efficiency of tools

Challenges

- Extend models and algorithms to cope with more systems. Infinite systems, parameterized systems, probabilistic systems, concurrent systems, timed systems, hybrid systems, ... See Modules 2.8 & 2.9
- Scale current tools to cope with real-size systems. Needs for modularity, abstractions, symmetries, ...

Outline

Introduction

Models
- Transition Systems
- ... with Variables
- Concurrent Systems
- Synchronization and Communication

Temporal Specifications

Satisfiability and Model Checking

More on Temporal Specifications
Model and abstractions

Example: Golden face

Each coin has a golden face and a silver face. At each step, we may flip simultaneously the 3 coins of a line, column or diagonal. Is it possible to have all coins showing its golden face? If yes, what is the smallest number of steps.
Model and Specification

Example: Man, Wolf, Goat, Cabbage

Model = Transition system

- State = who is on which side of the river
- Transition = crossing the river, M alone or with one of W, G, C
- Specification
  Safety: Never leave WG or GC alone
  Liveness: Take everyone to the other side of the river.
Transition system or Kripke structure

**Definition: TS**

\[ M = (S, \Sigma, T, I, \text{AP}, \ell) \]

- **S**: set of states (finite or infinite)
- **\( \Sigma \)**: set of actions
- **T**: set of transitions
- **I**: set of initial states
- **\text{AP}**: set of atomic propositions
- **\( \ell : S \rightarrow 2^{\text{AP}} \)**: labelling function.

Every discrete system may be described with a TS.

**Example: Digicode ABA**
Pb: How can we easily describe big systems?

**Description Languages (high level)**
- Programming languages
- Boolean circuits
- Modular description, e.g., parallel compositions
  problems: concurrency, synchronization, communication, atomicity, fairness, ...
- Petri nets (intermediate level)
- Transition systems (intermediate level)
  with variables, stacks, channels, ...
  synchronized products
- Logical formulae (low level)

**Operational semantics**
High level descriptions are translated (compiled) to low level (infinite) TS.
## Transition systems with variables

**Definition: TSV**

\[ M = (S, \Sigma, \mathcal{V}, (D_v)_{v \in \mathcal{V}}, T, I, \text{AP}, \ell) \]

- Finite description with \( S, \Sigma, \text{AP}, \ell \) as before
- \( \mathcal{V} \): set of (typed) variables, e.g., boolean, \([0..4], \mathbb{N}, \ldots\)
- Each variable \( v \in \mathcal{V} \) has a domain \( D_v \) (finite or infinite). Let \( D = \prod_{v \in \mathcal{V}} D_v \).
- Guard or Condition \( g \) with semantics \([g] \subseteq D \) (predicate)
  - Symbolic descriptions: \( x < 5, x + y = 10, \ldots \)
- Instruction or Update \( f \) with semantics \([f] : D \to D \) (or \([f] \subseteq D \times D \))
  - Symbolic descriptions: \( x := 0, x := (y + 1)^2, \ldots \)
- \( T \subseteq S \times (\text{Guard} \times \Sigma \times \text{Update}) \times S \)
  - Symbolic descriptions: \( s \xrightarrow{x<50,?\text{coin},x:=x+\text{coin}} s' \)
- \( I \subseteq S \times \text{Guard} \)
  - Symbolic descriptions: \( (s_0, x = 0) \)

### Example: Vending machine

- coffee: 50 cents, orange juice: 1 euro, ...
- possible coins: 10, 20, 50 cents
- we may shuffle coin insertions and drink selection
# Transition systems with variables

## Semantics: low level TS

- \( S' = S \times D \)
- \( I' = \{ (s, \nu) \mid \exists (s, g) \in I \text{ with } \nu \models g \} \)
- Transitions: \( T' \subseteq (S \times D) \times \Sigma \times (S \times D) \)

\[
\frac{g, a, f}{s} \xrightarrow{(s, \nu)} s' \land \nu \models g \quad \frac{(s, \nu) \xrightarrow{a} (s', f(\nu))}
\]

**SOS: Structural Operational Semantics**

- \( AP' \): we may use atomic propositions in \( AP \) or guards such as \( x > 0 \).

## Programs = Kripke structures with variables

- Program counter = states
- Instructions = transitions
- Variables = variables

## Example: GCD
TS with variables . . .

Example: Digicode

\[
\begin{align*}
\text{cpt} &= 0 \\
1 &\rightarrow A & \text{cpt} < n \\
&\rightarrow B, C & \text{cpt}++ \\
&\rightarrow \text{OPEN} \\
2 &\rightarrow B, C & \text{cpt} < n \\
&\rightarrow A & \text{cpt}++ \\
3 &\rightarrow A, C & \text{cpt}++ \\
&\rightarrow B, C & \text{cpt}++ \\
5 &\rightarrow \text{ERROR} \\
\end{align*}
\]
Only variables

The state is nothing but a special variable: \( s \in \mathcal{V} \) with domain \( D_s = S \).

**Definition:** TSV

\[
M = (\mathcal{V}, (D_v)_{v \in \mathcal{V}}, T, I, AP, \ell)
\]

- \( D = \prod_{v \in \mathcal{V}} D_v \),
- \( I \subseteq D, T \subseteq D \times D \)

Symbolic representations with logic formulae

- \( I \) given by a formula \( \psi(\nu) \)
- \( T \) given by a formula \( \varphi(\nu, \nu') \)
  - \( \nu \): values before the transition
  - \( \nu' \): values after the transition
- Often we use boolean variables only: \( D_v = \{0, 1\} \)
- Concise descriptions of boolean formulae with Binary Decision Diagrams.

Example: Boolean circuit: modulo 8 counter

\[
\begin{align*}
  b_0' &= \neg b_0 \\
  b_1' &= b_0 \oplus b_1 \\
  b_2' &= (b_0 \land b_1) \oplus b_2
\end{align*}
\]
Modular description of concurrent systems

\[ M = M_1 \parallel M_2 \parallel \cdots \parallel M_n \]

Semantics

- Various semantics for the parallel composition \( \parallel \)
- Various communication mechanisms between components: Shared variables, FIFO channels, Rendez-vous, ...
- Various restrictions

Atomic propositions are inherited from the local systems.

Example: Elevator with 1 cabin, 3 doors, 3 calling devices

- Cabin:
- Door for level \( i \):
- Call for level \( i \):
Synchronized products (semantics)

Definition: General product

- Components: \( M_i = (S_i, \Sigma_i, T_i, I_i, AP_i, \ell_i) \)
- Product: \( M = (S, \Sigma, T, I, AP, \ell) \) with
  \[
  S = \prod_i S_i, \quad \Sigma = \prod_i (\Sigma_i \cup \{\varepsilon\}), \quad \text{and} \quad I = \prod_i I_i
  \]
  \[
  T \text{ defined by } \forall i, \ (p_i \xrightarrow{a_i} q_i) \in T_i \lor (a_i = \varepsilon \land p_i = q_i)
  \]
  \[
  (p_1, \ldots, p_n) \xrightarrow{(a_1, \ldots, a_n)} (q_1, \ldots, q_n)
  \]
  \[
  AP = \bigcup_i AP_i \quad \text{and} \quad \ell(p_1, \ldots, p_n) = \bigcup_i \ell(p_i)
  \]

Synchronized products: restrictions of the general product.

Parallel compositions: 2 special cases

- Synchronous: \( \Sigma_{\text{sync}} = \prod_i \Sigma_i \)
- Asynchronous: \( \Sigma_{\text{async}} = \bigcup_i \Sigma_i' \) \[ \text{with } \Sigma_i' = \{\varepsilon\}^{i-1} \times \Sigma_i \times \{\varepsilon\}^{n-i} \]

Restrictions

- on states: \( S_{\text{restrict}} \subseteq S \)
- on labels: \( \Sigma_{\text{restrict}} \subseteq \Sigma \)
- on transitions: \( T_{\text{restrict}} \subseteq T \)
Shared variables

Definition: Asynchronous product + shared variables

\[ \overline{s} = (s_1, \ldots, s_n) \] denotes a tuple of states
\[ \nu \in D = \prod_{v \in \mathcal{V}} D_v \] is a valuation of variables.

Semantics (SOS)

\[ \nu \models g \land s_i \xrightarrow{g,a,f} s'_i \land s'_j = s_j \text{ for } j \neq i \]
\[ (\overline{s}, \nu) \xrightarrow{a} (\overline{s}', f(\nu)) \]

Example: Mutual exclusion for 2 processes satisfying

▶ **Safety:** never simultaneously in critical section (CS).
▶ **Liveness:** if a process wants to enter its CS, it eventually does.
▶ **Fairness:** if process 1 wants to enter its CS, then process 2 will enter its CS at most once before process 1 does.

using shared variables but without further restrictions: the atomicity is

▶ testing or reading or writing a single variable at a time
▶ no test-and-set: \( \{x = 0; x := 1\} \)
Peterson’s algorithm (1981)

Process $i$: 

// $i$ is not a variable

loop forever

req[$i$] := true; turn := 1-$i$

wait until (turn = $i$ or req[1-$i$] = false)

Critical section

req[$i$] := false

Exercise:

- Draw the concrete TS assuming the first two assignments are atomic.
- Is the algorithm still correct if we swap the first two assignments?
Atomicity

Example:

Initially $x = 1 \land y = 2$

Program $P_1$: $x := x + y \parallel y := x + y$

Program $P_2$: \[
\begin{pmatrix}
\text{Load}R_1, x \\
\text{Add}R_1, y \\
\text{Store}R_1, x \\
\end{pmatrix} \parallel \begin{pmatrix}
\text{Load}R_2, x \\
\text{Add}R_2, y \\
\text{Store}R_2, y \\
\end{pmatrix}
\]

Assuming each instruction is atomic, what are the possible results of $P_1$ and $P_2$?
Atomicity

Definition: Atomic statements: \texttt{atomic(ES)}

Elementary statements (no loops, no communications, no synchronizations)

\[
ES ::= \text{skip} | \text{await } c | x := e | ES ; ES | ES \oplus ES
| \text{when } c \text{ do } ES | \text{if } c \text{ then } ES \text{ else } ES
\]

Atomic statements: if the ES can be fully executed then it is executed in one step.

\[
(\bar{s}, \nu) \xrightarrow{ES} (\bar{s}', \nu') \quad \xrightarrow{\text{atomic(ES)}} (\bar{s}', \nu')
\]

Example: Atomic statements

\begin{itemize}
  \item \texttt{atomic}(x = 0; x := 1) \quad \text{(Test and set)}
  \item \texttt{atomic}(y := y - 1; \text{await}(y = 0); y := 1) \text{ is equivalent to } \text{await}(y = 1)
\end{itemize}
Communication by Rendez-vous

Restriction on transitions is universal but too low-level.

Definition: Rendez-vous

- \( !m \) sending message \( m \)
- \( ?m \) receiving message \( m \)
- **SOS: Structural Operational Semantics**

Local actions:

\[
\begin{align*}
\Delta \rightarrow_1 s' \\
(s_1, s_2) \rightarrow_1 (s', s_2)
\end{align*}
\]

Rendez-vous:

\[
\begin{align*}
(s_1, s_2) \rightarrow_1 (s'_1, s') \quad \text{and} \quad (s_1, s_2) \rightarrow_2 (s'_2, s')
\end{align*}
\]

- It is a restriction on actions.
- Essential feature of process algebra.

Example: Elevator with 1 cabin, 3 doors, 3 calling devices

- \( ?\text{up} \) is uncontrollable for the cabin
- \( ?\text{leave}_i \) is uncontrollable for door \( i \)
- \( ?\text{call}_0 \) is uncontrollable for the system
Example: Leader election

We have $n$ processes on a directed ring, each having a unique $id \in \{1, \ldots, n\}$.

```
send(id)
loop forever
  receive(x)
  if (x = id) then STOP fi
  if (x > id) then send(x)
```
Definition: Channels

- Declaration:
  - \( c : \text{channel} [k] \text{ of bool size } k \)
  - \( c : \text{channel} [\infty] \text{ of int unbounded} \)
  - \( c : \text{channel} [0] \text{ of colors Rendez-vous} \)

- Primitives:
  - \( \text{empty}(c) \)
  - \( c!e \) add the value of expression \( e \) to channel \( c \)
  - \( c?x \) read a value from \( c \) and assign it to variable \( x \)

- Domain: Let \( D_m \) be the domain for a single message.
  - \( D_c = D^{\leq k}_m \) size \( k \)
  - \( D_c = D^{\ast}_m \) unbounded
  - \( D_c = \{ \varepsilon \} \) Rendez-vous

- Politics: FIFO, LIFO, BAG, . . .
Channels

Semantics: (lossy) FIFO

Send

\[
\begin{align*}
\text{Send} & \quad s_i \xrightarrow{c!e} s_i' \land \nu'(c) = \nu(e) \cdot \nu(c) \\
(\bar{s}, \nu) & \xrightarrow{c!e} (\bar{s}', \nu')
\end{align*}
\]

Receive

\[
\begin{align*}
\text{Receive} & \quad s_i \xrightarrow{c?x} s_i' \land \nu(c) = \nu'(c) \cdot \nu'(x) \\
(\bar{s}, \nu) & \xrightarrow{c?e} (\bar{s}', \nu')
\end{align*}
\]

Lossy send

\[
\begin{align*}
\text{Lossy send} & \quad s_i \xrightarrow{c!e} s_i' \\
(\bar{s}, \nu) & \xrightarrow{c!e} (\bar{s}', \nu)
\end{align*}
\]

Implicit assumption: all variables that do not occur in the premise are not modified.

Exercises:

1. Implement a FIFO channel using rendez-vous with an intermediary process.
2. Give the semantics of a LIFO channel.
3. Model the alternating bit protocol (ABP) using a lossy FIFO channel.
   Fairness assumption: For each channel, if infinitely many messages are sent, then infinitely many messages are delivered.
High-level descriptions

Summary

- Sequential program = transition system with variables
- Concurrent program with shared variables
- Concurrent program with Rendez-vous
- Concurrent program with FIFO communication
- Petri net
- ...

Remark: (Un)decidability

- Automata with 2 integer variables = Turing powerful
  Restriction to variables taking values in finite sets
- Asynchronous communication: unbounded fifo channels = Turing powerful
  Restriction to bounded channels or lossy channels

Remark: Some infinite state models are decidable

- Petri nets. Several unbounded integer variables but no zero-test.
- Pushdown automata. Model for recursive procedure calls.
- Timed automata.
- ...
Outline

Introduction

Models

3 Temporal Specifications
  • General Definitions
  • (Linear) Temporal Specifications
  • Branching Temporal Specifications
  • CTL*
  • CTL

Satisfiability and Model Checking

More on Temporal Specifications
Static and dynamic properties

Example: Static properties

Mutual exclusion
Safety properties are often static.
They can be reduced to reachability.

Example: Dynamic properties

Every elevator request should be eventually granted.

The elevator should not cross a level for which a call is pending without stopping.
Temporal Structures

**Definition: Flows of time**

A *flow of time* is a strict order \((\mathbb{T}, <)\) where \(\mathbb{T}\) is the nonempty set of *time points* and \(<\) is an irreflexive transitive relation on \(\mathbb{T}\).

**Example: Flows of time**

- \((\{0, \ldots, n\}, <)\): Finite runs of sequential systems.
- \((\mathbb{N}, <)\): Infinite runs of sequential systems.
- \((\mathbb{R}, <)\): runs of real-time sequential systems.
- **Trees**: Finite or infinite run-trees of sequential systems.
- **Mazurkiewicz traces**: runs of distributed systems (rendez-vous).
- **Message sequence charts**: runs of distributed systems (FIFO).
- and also \((\mathbb{Z}, <)\) or \((\mathbb{Q}, <)\) or \((\omega^2, <), \ldots\)

**Definition: Temporal Structures**

Let \(\text{AP}\) be a set of atoms (atomic propositions) and let \(\mathcal{C}\) be a class of time flows. A *temporal structure* over \((\mathcal{C}, \text{AP})\) is a triple \((\mathbb{T}, <, \lambda)\) where \((\mathbb{T}, <)\) is a time flow in \(\mathcal{C}\) and \(\lambda: \mathbb{T} \rightarrow 2^{\text{AP}}\) labels time points with atomic propositions.

The temporal structure \((\mathbb{T}, <, \lambda)\) is also denoted \((\mathbb{T}, <, h)\) where \(h: \text{AP} \rightarrow 2^{\mathbb{T}}\) assigns time points to atomic propositions: \(h(p) = \{t \in \mathbb{T} \mid p \in \lambda(t)\}\) for \(p \in \text{AP}\).
Linear behaviors and specifications

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure (we omit actions: $T \subseteq S \times S$).

**Definition: Runs as temporal structures**

An infinite run $\sigma = s_0s_1s_2 \cdots$ of $M$ with $(s_i, s_{i+1}) \in T$ for all $i \geq 0$ defines a **linear** temporal structure $\ell(\sigma) = (\mathbb{N}, <, \lambda)$ where $\lambda(i) = \ell(s_i)$ for $i \in \mathbb{N}$.

Such a temporal structure can be seen as an infinite word over $\Sigma = 2^{AP}$:

$\ell(\sigma) = \ell(s_0)\ell(s_1)\ell(s_2) \cdots \in \Sigma^\omega$

Linear specifications only depend on runs.

Example: The printer manager is starvation free.

On each run, whenever some process requests the printer, it eventually gets it.

**Remark:**

Two Kripke structures having the same linear temporal structures satisfy the same linear specifications.
Branching behaviors and specifications

The system has an infinite active run, along which it may always reach an inactive state.

Definition: Computation-tree or run-tree: unfolding of the TS

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure. Wlog. $I = \{s_0\}$ is a singleton. Let $D$ be a finite set with $|D|$ the outdegree of the transition relation $T$.

The computation-tree of $M$ is an unordered tree $t: D^* \to S$ (partial map) s.t.

- $t(\varepsilon) = s_0$, 
- For every node $u \in \text{dom}(t)$ labelled $s = t(u)$, if $T(s) = \{s_1, \ldots, s_k\}$ then $u$ has exactly $k$ children which are labelled $s_1, \ldots, s_k$.

Associated temporal structure $\ell(t) = (\text{dom}(t), <, \lambda)$ where

- $<$ is the strict prefix relation over $D^*$,
- and $\lambda(u) = \ell(t(u))$ for $u \in \text{dom}(t)$.

(Linear) runs of $M$ are branches of the computation-tree $t$. 
First-order Specifications

Definition: Syntax of $\text{FO}(\text{AP}, <)$

Let $\text{Var} = \{x, y, \ldots\}$ be first-order variables.

$$\varphi ::= \bot \mid p(x) \mid x = y \mid x < y \mid \neg \varphi \mid \varphi \lor \varphi \mid \exists x \varphi$$

where $p \in \text{AP}$.

Definition: Semantics of $\text{FO}(\text{AP}, <)$

Let $w = (\mathbb{T}, <, \lambda)$ be a temporal structure over $\text{AP}$.
Let $\nu : \text{Var} \rightarrow \mathbb{T}$ be an assignment of first-order variables to time points.

$$w, \nu \models p(x) \quad \text{if} \quad p \in \lambda(\nu(x))$$
$$w, \nu \models x = y \quad \text{if} \quad \nu(x) = \nu(y)$$
$$w, \nu \models x < y \quad \text{if} \quad \nu(x) < \nu(y)$$
$$w, \nu \models \exists x \varphi \quad \text{if} \quad w, \nu[x \mapsto t] \models \varphi \text{ for some } t \in \mathbb{T}$$

where $\nu[x \mapsto t]$ maps $x$ to $t$ and $y \neq x$ to $\nu(y)$.

Previous specifications can be written in $\text{FO}(<)$ (except the branching one).
First-order vs Temporal

### First-order logic
- FO(\(<\)) has a good expressive power
  - ... but FO(\(<\))-formulae are not easy to write and to understand.
- FO(\(<\)) is decidable
  - ... but satisfiability and model checking are non elementary.

### Temporal logics
- no variables: time is implicit.
- quantifications and variables are replaced by modalities.
- Usual specifications are easy to write and read.
- Good complexity for satisfiability and model checking problems.
- Good expressive power.

Linear Temporal Logic (LTL) over \((\mathbb{N}, <, AP)\) introduced by Pnueli (1977) as a convenient specification language for verification of systems.
**Temporal Specifications**

**Definition: Syntax of TL(AP, SU, SS)**

\[ \varphi ::= \bot \mid p \ (p \in AP) \mid \neg \varphi \mid \varphi \lor \varphi \mid \varphi \ SU \ \varphi \mid \varphi \ SS \ \varphi \]

**Definition: Semantics:**  \( w = (\mathbb{T}, <, \lambda) \) temporal structure and \( i \in \mathbb{T} \)

- \( w, i \models p \) if \( p \in \lambda(i) \)
- \( w, i \models \neg \varphi \) if \( w, i \not\models \varphi \)
- \( w, i \models \varphi \lor \psi \) if \( w, i \models \varphi \) or \( w, i \models \psi \)
- \( w, i \models \varphi \ SU \ \psi \) if \( \exists \ k \ i < k \) and \( w, k \models \psi \) and \( \forall j \ (i < j < k \rightarrow w, j \models \varphi) \)
- \( w, i \models \varphi \ SS \ \psi \) if \( \exists \ k \ i > k \) and \( w, k \models \psi \) and \( \forall j \ (i > j > k \rightarrow w, j \models \varphi) \)

Previous specifications can be written in TL(AP, SU, SS) (except the branching one).

**Theorem:** \( TL \subseteq FO^3 \)

For each \( \varphi \in TL(AP, SU, SS) \) we can construct an equivalent formula with one free variable \( \tilde{\varphi}(x) \in FO^3(AP, <) \).
Temporal Specifications

Definition: non-strict versions of until and since

\[
\varphi U \psi \overset{\text{def}}{=} \psi \lor (\varphi \land \varphi \text{SU} \psi) \quad \varphi S \psi \overset{\text{def}}{=} \psi \lor (\varphi \land \varphi \text{SS} \psi)
\]

\[
w, i \models \varphi U \psi \quad \text{if} \quad \exists k \ i < k \text{ and } w, k \models \psi \text{ and } \forall j \ (i < j < k \rightarrow w, j \models \varphi)
\]

\[
w, i \models \varphi S \psi \quad \text{if} \quad \exists k \ i > k \text{ and } w, k \models \psi \text{ and } \forall j \ (i > j > k \rightarrow w, j \models \varphi)
\]

Definition: Derived modalities

\[
X \varphi \overset{\text{def}}{=} \bot \text{SU} \varphi \quad \text{Next} \quad Y \varphi \overset{\text{def}}{=} \bot \text{SS} \varphi \quad \text{Yesterday}
\]

\[
w, i \models X \varphi \quad \text{if} \quad \exists k \ i < k \text{ and } w, k \models \varphi \text{ and } \neg \exists j \ (i < j < k)
\]

\[
w, i \models Y \varphi \quad \text{if} \quad \exists k \ i > k \text{ and } w, k \models \varphi \text{ and } \neg \exists j \ (i > j > k)
\]

\[
\begin{align*}
SF \varphi & \overset{\text{def}}{=} T \text{SU} \varphi \\
F \varphi & \overset{\text{def}}{=} T \text{U} \varphi \\
G \varphi & \overset{\text{def}}{=} \neg F \neg \varphi \\
SP \varphi & \overset{\text{def}}{=} T \text{SS} \varphi \\
P \varphi & \overset{\text{def}}{=} T \text{S} \varphi \\
H \varphi & \overset{\text{def}}{=} \neg P \neg \varphi
\end{align*}
\]

\[
\begin{align*}
\varphi \text{W} \psi & \overset{\text{def}}{=} (G \varphi) \lor (\varphi \text{U} \psi) \quad \text{Weak Until} \\
\varphi \text{R} \psi & \overset{\text{def}}{=} (G \psi) \lor (\psi \text{U} (\varphi \land \psi)) \quad \text{Release}
\end{align*}
\]
Example: Specifications on the time flow \((\mathbb{N}, <)\)

- **Safety**: \(G\) good
- **MutEx**: \(\neg F(crit_1 \land crit_2)\)
- **Liveness**: \(G F active\)
- **Response**: \(G(request \rightarrow F grant)\)
- **Response’**: \(G(request \rightarrow (\neg request SU grant))\)
- **Release**: \(reset R alarm\)
- **Strong fairness**: \((G F request) \rightarrow (G F grant)\)
- **Weak fairness**: \((F G request) \rightarrow (G F grant)\)
- **Stability**: \(G \neg p \lor (\neg p U G p)\)
Definition: discrete linear time flows \((\mathbb{T}, <)\)

A linear time flow is **discrete** if \(SF_{\mathbb{T}} \rightarrow X_{\mathbb{T}}\) and \(SP_{\mathbb{T}} \rightarrow Y_{\mathbb{T}}\) are valid formulae.

\((\mathbb{N}, <)\) and \((\mathbb{Z}, <)\) are discrete.

\((\mathbb{Q}, <)\) and \((\mathbb{R}, <)\) are **not** discrete.

**Exercise:** For discrete linear time flows \((\mathbb{T}, <)\)

\[
\begin{align*}
\varphi \text{ SU } \psi & \equiv X(\varphi \text{ U } \psi) & -X \varphi & \equiv -X_{\mathbb{T}} \lor X_{\mathbb{T}} \neg \varphi \\
\varphi \text{ SS } \psi & \equiv Y(\varphi \text{ S } \psi) & -Y \varphi & \equiv -Y_{\mathbb{T}} \lor Y_{\mathbb{T}} \neg \varphi \\
\neg(\varphi \text{ U } \psi) & \equiv (G \neg \psi) \lor (\neg \psi \text{ U } (\neg \varphi \land \neg \psi)) & \equiv \neg \psi \text{ W } (\neg \varphi \land \neg \psi) & \equiv \neg \varphi \text{ R } \neg \psi
\end{align*}
\]

**Remark:** Dense time flow \(\mathbb{T} = \mathbb{Q}\) or \(\mathbb{T} = \mathbb{R}\)

\((\varphi \text{ U } \psi)\) does not imply \(\neg \varphi \text{ R } \neg \psi\).

For instance, \(w = (\mathbb{T}, <, \ell)\) with \(\mathbb{T} = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}\) with \(\ell(0) = \{p\}\), \(\ell(\frac{1}{2n}) = \{p\}\) and \(\ell(\frac{1}{2n+1}) = \{q\}\). Then, \(w, 0 \models \neg(p \text{ U } q)\) and \(w, 0 \not\models \neg p \text{ R } \neg q\).
Model checking for linear behaviors

Definition: Model checking problem

Input: A Kripke structure $M = (S, T, I, AP, \ell)$
A formula $\varphi \in \text{LTL}(AP, SU, SS)$

Question: Does $M \models \varphi$?

- **Universal MC:** $M \models \forall \varphi$ if $\ell(\sigma), 0 \models \varphi$ for all initial infinite runs $\sigma$ of $M$.
- **Existential MC:** $M \models \exists \varphi$ if $\ell(\sigma), 0 \models \varphi$ for some initial infinite run $\sigma$ of $M$.

$$M \models \forall \varphi \iff M \not\models \exists \neg \varphi$$

Theorem [11, Sistla, Clarke 85], [10, Lichtenstein & Pnueli 85]

The Model checking problem for LTL is PSPACE-complete. Proof later
Weaknesses of linear behaviors

Example:

$\varphi$: Whenever $p$ holds, it is possible to reach a state where $q$ holds.

$\varphi$ cannot be checked on linear behaviors.

We need to consider the computation-trees.

Remark: FO definable on the computation tree

$$\forall x \ (p(x) \rightarrow \exists y \ (x < y \land q(y)))$$
Weaknesses of FO specifications

Example:

\( \psi \): The system has an infinite active run, along which it may always reach an inactive state.

\( \psi \) cannot be expressed in FO.

We need quantifications on runs:  
\[
\psi = \text{EG}(\text{Active} \land \text{EF} \neg \text{Active})
\]

- E: for some infinite run
- A: for all infinite runs
**MSO Specifications**

**Definition: Syntax of MSO(AP, <)**

\[ \varphi ::= \bot \mid p(x) \mid x = y \mid x < y \mid x \in X \mid \neg \varphi \mid \varphi \lor \varphi \mid \exists x \, \varphi \mid \exists X \, \varphi \]

where \( p \in AP \), \( x, y \) are first-order variables and \( X \) is a second-order variable.

**Definition: Semantics of MSO(AP, <)**

Let \( w = (T, <, \lambda) \) be a temporal structure over \( AP \).

An assignment \( \nu \) maps first-order variables to time points in \( T \) and second-order variables to sets of time points.

The semantics of first-order constructs is unchanged.

\[ w, \nu \models x \in X \text{ if } \nu(x) \in \nu(X) \]
\[ w, \nu \models \exists X \, \varphi \text{ if } w, \nu[X \mapsto T] \models \varphi \text{ for some } T \subseteq T \]

where \( \nu[X \mapsto T] \) maps \( X \) to \( T \) and keeps unchanged the other assignments.
MSO vs Temporal

**MSO logic**

- MSO(<) has a good expressive power
  - ... but MSO(<)-formulae are not easy to write and to understand.
- MSO(<) is decidable on computation trees
  - ... but satisfiability and model checking are non elementary.

**We need a temporal logic**

- with no explicit variables,
- allowing quantifications over runs,
- usual specifications should be easy to write and read,
- with good complexity for satisfiability and model checking problems,
- with good expressive power.

Computation Tree Logic CTL* introduced by Emerson & Halpern (1986).
Definition: Syntax of the Computation Tree Logic $\text{CTL}^*$\((\text{AP}, \text{SU})\)

\[ \phi ::= \bot \mid p \ (p \in \text{AP}) \mid \neg \phi \mid \phi \lor \phi \mid \phi \text{SU} \phi \mid E \phi \mid A \phi \]

We may also add the past modality SS. Two implicit free variables.

Definition: Semantics of $\text{CTL}^*\((\text{AP}, \text{SU})\)$

Let \( M = (S, T, I, \text{AP}, \ell) \) be a Kripke structure (encodes the computation tree \( T \)). Let \( \sigma = s_0s_1s_2 \cdots \) be an infinite run of \( M \) (infinite branch of \( T \)). \( i \in \mathbb{N} \) (current position in the run \( \sigma \)).

\[
\begin{align*}
M, \sigma, i \models p & \quad \text{if} \quad p \in \ell(s_i) \\
M, \sigma, i \models \phi \text{SU} \psi & \quad \text{if} \quad \exists k > i, \ M, \sigma, k \models \psi \quad \text{and} \quad \forall i < j < k, \ M, \sigma, j \models \phi \\
M, \sigma, i \models E\phi & \quad \text{if} \quad M, \sigma', i \models \phi \quad \text{for some} \quad \text{infinite run} \ \sigma' \quad \text{such that} \quad \sigma'[i] = \sigma[i] \\
M, \sigma, i \models A\phi & \quad \text{if} \quad M, \sigma', i \models \phi \quad \text{for all} \quad \text{infinite runs} \ \sigma' \quad \text{such that} \quad \sigma'[i] = \sigma[i]
\end{align*}
\]

where \( \sigma[i] = s_0 \cdots s_i \).

Remark:

- \( \sigma'[i] = \sigma[i] \) means that future is branching but past is not.
CTL* (Emerson & Halpern 86)

**Example: Some specifications**

- **EF \( \varphi \):** \( \varphi \) is possible
  - FO-definable on CT
- **AG \( \varphi \):** \( \varphi \) is an invariant
  - FO-definable on CT
- **AF \( \varphi \):** \( \varphi \) is unavoidable
  - not FO-definable on CT
- **EG \( \varphi \):** \( \varphi \) holds globally along some path
  - not FO-definable on CT

**Remark: Some equivalences**

- **A \( \varphi \) \equiv \neg E \neg \varphi**
- **E(\( \varphi \lor \psi \)) \equiv E \( \varphi \lor E \psi \)**
- **A(\( \varphi \land \psi \)) \equiv A \( \varphi \land A \psi \)**

**Theorem: CTL* \( \subseteq \) MSO**

For each \( \varphi \in \text{CTL}^*(\text{AP, SU}) \) we can construct an equivalent formula with two free variables \( \tilde{\varphi}(X, x) \in \text{MSO}(\text{AP, <}) \).

For all computation tree \( T \), infinite branch \( B \) of \( T \) and position \( i \) in \( B \), we have

\[
T, B, i \models \varphi \text{ iff } T, X \mapsto B, x \mapsto i \models \tilde{\varphi}.
\]
Model checking of $\text{CTL}^*$

**Definition: Existential and universal model checking**

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure and $\varphi \in \text{CTL}^*$ a formula.

$M \models \exists \varphi$ if $M, \sigma, 0 \models \varphi$ for some initial infinite run $\sigma$ of $M$.

$M \models \forall \varphi$ if $M, \sigma, 0 \models \varphi$ for all initial infinite runs $\sigma$ of $M$.

Remark: $M \models \forall \varphi$ iff $M \not\models \exists \neg \varphi$

Remark: Often, formulas start with E or A and if $M$ has a single initial state, we do not need to distinguish between $\models \exists$ and $\models \forall$.

**Definition: Model checking problems $\text{MC}_{\text{CTL}^*}^\forall$ and $\text{MC}_{\text{CTL}^*}^\exists$**

Input: A Kripke structure $M = (S, T, I, AP, \ell)$ and a formula $\varphi \in \text{CTL}^*$

Question: Does $M \models \forall \varphi$? or Does $M \models \exists \varphi$?

**Theorem:**

The model checking problem for $\text{CTL}^*$ is PSPACE-complete. Proof later
State formulae and path formulae

Definition: State formulae

$\varphi \in \text{CTL}^*$ is a state formula if $\forall M, \sigma, \sigma', i, j$ such that $\sigma(i) = \sigma'(j)$ we have

$$M, \sigma, i \models \varphi \iff M, \sigma', j \models \varphi$$

If $\varphi$ is a state formula and $M = (S, T, I, \text{AP}, \ell)$, define

$$M, s \models \varphi \text{ if } M, \sigma, 0 \models \varphi \text{ for some infinite run } \sigma \text{ of } M \text{ with } \sigma(0) = s$$

and

$$[\varphi]^M = \{ s \in S \mid M, s \models \varphi \}$$

Example: State formulae

Atomic propositions are state formulae:

$$[p] = \{ s \in S \mid p \in \ell(s) \}$$

State formulae are closed under boolean connectives.

$$[\neg \varphi] = S \setminus [\varphi]$$

$$[\varphi_1 \lor \varphi_2] = [\varphi_1] \cup [\varphi_2]$$

Formulae of the form $E \varphi$ or $A \varphi$ are state formulae, provided $\varphi$ is future.

Remark:

$$M \models \exists \varphi \text{ iff } I \cap [E \varphi] \neq \emptyset$$

$$M \models \forall \varphi \text{ iff } I \subseteq [A \varphi]$$

Definition: Alternative syntax

State formulae

$$\varphi ::= \bot \mid p \ (p \in \text{AP}) \mid \neg \varphi \mid \varphi \lor \varphi \mid E \psi \mid A \psi$$

Path formulae

$$\psi ::= \varphi \mid \neg \psi \mid \psi \lor \psi \mid \psi \text{ SU } \psi$$
Definition: Computation Tree Logic $\text{CTL}(\text{AP, X, U})$

Syntax:

$$\varphi ::= \bot \mid p \ (p \in \text{AP}) \mid \neg \varphi \mid \varphi \lor \varphi \mid \text{EX } \varphi \mid \text{AX } \varphi \mid \text{E } \varphi \text{ U } \varphi \mid \text{A } \varphi \text{ U } \varphi$$

The semantics is inherited from $\text{CTL}^\ast$.

Remark: $\text{E } \varphi \text{ U } \psi$ is not FO-definable on the computation tree.

Remark: All CTL formulae are state formulae

$$[[\varphi]]^M = \{s \in S \mid M, s \models \varphi\}$$

Examples: Macros

- $\text{EF } \varphi = \text{E } \top \text{ U } \varphi$ and $\text{AG } \varphi = \neg \text{EF } \neg \varphi$
- $\text{AF } \varphi = \text{A } \top \text{ U } \varphi$ and $\text{EG } \varphi = \neg \text{AF } \neg \varphi$
- $\text{AG}(\text{req } \rightarrow \text{ EF grant})$
- $\text{AG}(\text{req } \rightarrow \text{ AF grant})$
Definition: Semantics

All CTL-formulae are state formulae. Hence, we have a simpler semantics.
Let \( M = (S, T, I, AP, \ell) \) be a Kripke structure without deadlocks and let \( s \in S \).

\[
\begin{align*}
M, s \models p & \quad \text{if} \quad p \in \ell(s) \\
M, s \models \text{EX} \varphi & \quad \text{if} \quad \exists s \to s' \text{ with } M, s' \models \varphi \\
M, s \models \text{AX} \varphi & \quad \text{if} \quad \forall s \to s' \text{ we have } M, s' \models \varphi \\
M, s \models \text{E} \varphi \text{ U } \psi & \quad \text{if} \quad \exists s = s_0 \to s_1 \to s_2 \to \cdots s_k \text{ finite path, with } \\
& \quad M, s_k \models \psi \text{ and } M, s_j \models \varphi \text{ for all } 0 \leq j < k \\
M, s \models \text{A} \varphi \text{ U } \psi & \quad \text{if} \quad \forall s = s_0 \to s_1 \to s_2 \to \cdots \text{ infinite paths, } \exists k \geq 0 \text{ with } \\
& \quad M, s_k \models \psi \text{ and } M, s_j \models \varphi \text{ for all } 0 \leq j < k
\end{align*}
\]

Theorem: CTL \subseteq MSO

For each \( \varphi \in \text{CTL}(AP, X, U) \) we can construct an equivalent formula with one free variable \( \tilde{\varphi}(x) \in \text{MSO}(AP, <) \).

NB. Here models are computation trees.
Example:

$$\begin{align*}
[\text{EX } p] &= \\
[\text{AX } p] &= \\
[\text{EF } p] &= \\
[\text{AF } p] &= \\
[\text{E } q \cup r] &= \\
[\text{A } q \cup r] &=
\end{align*}$$
Remark: Equivalent formulae

- \( AX \varphi \equiv \neg EX \neg \varphi \), assuming no deadlocks
- \( \neg(\varphi U \psi) \equiv G \neg \psi \lor (\neg \psi U (\neg \varphi \land \neg \psi)) \)
- \( A \varphi U \psi \equiv \neg EG \neg \psi \land \neg E(\neg \psi U (\neg \varphi \land \neg \psi)) \)
- \( AG(req \rightarrow F\ grant) \equiv AG(req \rightarrow AF\ grant) \)
- \( AGF\varphi \equiv AG AF\varphi \)
- \( EFG\varphi \equiv EF EG\varphi \)
- \( EG AF\varphi \implies EGF\varphi \implies EG EF\varphi \)
  but \( M_1 \models EGF\varphi, \ M_1 \not\models EG AF\varphi \) and \( M_2 \models EG EF\varphi, \ M_2 \not\models EGF\varphi \).
- \( EG AF\varphi \not\equiv EGF\varphi \not\equiv EG EF\varphi \)
- \( AF EG\varphi \not\equiv AFG\varphi \not\equiv AF AG\varphi \)
- \( EG EX\varphi \not\equiv EGX\varphi \not\equiv EG AX\varphi \)
Model checking of CTL

Definition: Existential and universal model checking

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure and $\varphi \in \text{CTL}$ a formula.

$M \models \exists \varphi$ if $M, s \models \varphi$ for some $s \in I$.

$M \models \forall \varphi$ if $M, s \models \varphi$ for all $s \in I$.

Remark:

$M \models \exists \varphi$ iff $I \cap [\varphi] \neq \emptyset$

$M \models \forall \varphi$ iff $I \subseteq [\varphi]$

$M \models \forall \varphi$ iff $M \not\models \exists \neg \varphi$

Definition: Model checking problems $\text{MC}_{\text{CTL}}^{\forall}$ and $\text{MC}_{\text{CTL}}^{\exists}$

Input: A Kripke structure $M = (S, T, I, AP, \ell)$ and a formula $\varphi \in \text{CTL}$

Question: Does $M \models \forall \varphi$? or Does $M \models \exists \varphi$?

Theorem:

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure and $\varphi \in \text{CTL}$ a formula.

The model checking problem $M \models \exists \varphi$ is decidable in time $O(|M| \cdot |\varphi|)$

More on Temporal Specifications
Theorem

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure and $\varphi \in \text{CTL}$ a formula. The set $[[\varphi]] = \{s \in S \mid M, s \models \varphi\}$ can be computed in time $O(|M| \cdot |\varphi|)$. Hence, the model checking problem $M \models \exists \varphi$ is decidable in time $O(|M| \cdot |\varphi|)$.

Proof:

Compute $[[\varphi]]$ by induction on the formula.

The set $[[\varphi]]$ is represented by a boolean array: $L[s] = \top$ if $s \in [[\varphi]]$.

For each $t \in S$, the set $T^{-1}(t)$ is represented as a list.

$T^{-1}$ is an array of lists, its size is $|S| + |T|$.

for all $t \in S$ do for all $s \in T^{-1}(t)$ do ... od takes time $O(|S| + |T|)$. 
Model checking of CTL

Definition: function semantics(\(\varphi\)) returns boolean array \(L\)

- **case** \(\varphi = p \in \text{AP}\)
  
  for all \(s \in S\) do \(L[s] := (p \in \ell(s))\) od \(O(|S|)\)

- **case** \(\varphi = \neg \varphi_1\)
  
  \(L_1 := \text{semantics}(\varphi_1)\)
  
  for all \(s \in S\) do \(L[s] := \neg L_1[s]\) od \(O(|S|)\)

- **case** \(\varphi = \varphi_1 \lor \varphi_2\)
  
  \(L_1 := \text{semantics}(\varphi_1); L_2 := \text{semantics}(\varphi_2)\)
  
  for all \(s \in S\) do \(L[s] := L_1[s] \lor L_2[s]\) od \(O(|S|)\)

- **case** \(\varphi = \text{EX} \varphi_1\)
  
  \(L_1 := \text{semantics}(\varphi_1)\)
  
  for all \(s \in S\) do \(L[s] := \bot\) od \(O(|S|)\)
  
  for all \(t \in S\) do if \(L_1[t]\) then for all \(s \in T^{-1}(t)\) do \(L[s] := \top\) \(O(|S| + |T|)\)

- **case** \(\varphi = \text{AX} \varphi_1\)
  
  \(L_1 := \text{semantics}(\varphi_1)\)
  
  for all \(s \in S\) do \(L[s] := \top\) od \(O(|S|)\)
  
  for all \(t \in S\) do if \(\neg L_1[t]\) then for all \(s \in T^{-1}(t)\) do \(L[s] := \bot\) \(O(|S| + |T|)\)
Model checking of CTL

Definition: function semantics(ϕ) returns boolean array L

case ϕ = E ϕ₁ U ϕ₂
    L₁ := semantics(ϕ₁); L₂ := semantics(ϕ₂)
    for all s ∈ S do
        L[s] := L₂[s]
        if L₂[s] then Todo.add(s) // Todo is implemented with a stack
    while Todo ≠ ∅ do
        t := Todo.remove()
        for all s ∈ T⁻¹(t) do
            if L₁[s] ∧ ¬L[s] then Todo.add(s); L[s] := ⊤
        od

Invariant 1: [ϕ₂] U Todo ⊆ L ⊆ [E ϕ₁ U ϕ₂]

O(|S| + |T|)
O(|S|)
|S| times
O(1)
|T| times
O(1)
Model checking of $\text{CTL}$

Definition: function semantics($\varphi$) returns boolean array $L$

\[
\begin{align*}
\text{case } \varphi &= \texttt{A} \varphi_1 \texttt{U} \varphi_2 \\
L_1 &:= \text{semantics}(\varphi_1); \ L_2 := \text{semantics}(\varphi_2) \\
\text{for all } s \in S \text{ do} & \quad O(|S|) \\
\quad L[s] := L_2[s] & \quad O(|S|) \\
\quad \text{if } L_2[s] \text{ then } \text{Todo}.add(s) & \quad O(|S|) \\
\text{for all } s \in S \text{ do} & \quad O(|S|) \\
\quad d[s] := 0 & \quad O(|S|) \\
\text{for all } t \in S \text{ do for all } s \in T^{-1}(t) \text{ do} & \quad O(|S| + |T|) \\
\quad d[s] := d[s] + 1 & \quad |S| \text{ times} \\
\text{while } \text{Todo} \neq \emptyset \text{ do} & \quad O(1) \\
\text{Invariant 1: } & \quad \forall s \in S, \ |T(s)| - d[s] = |T(s) \cap (L \setminus \text{Todo})| \\
\text{Invariant 2: } & \quad [\varphi_2] \cup \text{Todo} \subseteq L \subseteq [\texttt{A} \varphi_1 \texttt{U} \varphi_2] \\
\quad t := \text{Todo}.remove() & \quad O(1) \\
\quad \text{for all } s \in T^{-1}(t) \text{ do} & \quad |T| \text{ times} \\
\quad \quad d[s] := d[s] - 1 & \quad O(1) \\
\quad \quad \text{if } L_1[s] \land \neg L[s] \land d[s] = 0 \text{ then } & \quad O(1) \\
\quad \quad \text{Todo}.add(s); \ L[s] := \top & \quad O(1) \\
\text{od}
\end{align*}
\]
Definition: \textsc{SAT}(CTL)

Input: A formula $\varphi \in \text{CTL}$

Question: Existence of a model $M$ and a state $s$ such that $M, s \models \varphi$?

Theorem: Complexity

- The model checking problem for CTL is PTIME-complete.
- The satisfiability problem for CTL is EXPSPACE-complete.
Example: Fairness

Only fair runs are of interest

- Each process is enabled infinitely often: $\bigwedge_i G F \text{run}_i$
- No process stays ultimately in the critical section: $\bigwedge_i \neg F G \text{cs}_i = \bigwedge_i G F \neg \text{cs}_i$

Definition: Fair Kripke structure

$M = (S, T, I, AP, \ell, F_1, \ldots, F_n)$ with $F_i \subseteq S$.

An infinite run $\sigma$ is fair if it visits infinitely often each $F_i$. 
**Definition: Syntax of fair-CTL**

\[ \varphi ::= \bot \mid p \ (p \in AP) \mid \neg \varphi \mid \varphi \lor \varphi \mid E_f X \varphi \mid A_f X \varphi \mid E_f \varphi U \varphi \mid A_f \varphi U \varphi \]

**Definition: Semantics as a fragment of CTL*\(^*\)**

Let \( M = (S, T, I, AP, \ell, F_1, \ldots, F_n) \) be a fair Kripke structure.

Let, 
\[ E_f \varphi = E(\text{FairRun} \land \varphi) \quad \text{and} \quad A_f \varphi = A(\text{FairRun} \rightarrow \overline{\varphi}) \]

where 
\[ \text{FairRun} = \bigwedge_i GF F_i \]

Then, 
\[ [\varphi]_f = [\overline{\varphi}] \]

**Lemma:** \( \text{CTL}_f \) cannot be expressed in CTL
Theorem

The model checking problem for $\text{CTL}_f$ is decidable in time $O(|M| \cdot |\varphi|)$

Proof: Computation of FairStates = \{ $s \in S$ | $M, s \models E_f \top$ \}

Compute the SCC of $M$ in time $O(|M|)$, e.g., with Tarjan’s algorithm.
Let $S'$ be the union of the (non trivial) SCCs which intersect each $F_i$.
Then, FairStates is the set of states that can reach $S'$: FairStates = $[EF S']$.
Note that reachability can be computed in linear time.

Proof: Reductions

$E_f X \varphi = E X (\text{FairStates} \land \varphi)$ and $E_f \varphi U \psi = E \varphi U (\text{FairStates} \land \psi)$

It remains to deal with $A_f \varphi U \psi$. We have

$A_f \varphi U \psi = \neg E_f G \neg \psi \land \neg E_f (\neg \psi U (\neg \varphi \land \neg \psi))$

Hence, we only need to compute the semantics of $E_f G \varphi$.
Let $M_\varphi$ be the restriction of $M$ to $[\varphi]_f$. Then,

$M, s \models E_f G \varphi$ iff $M_\varphi, s \models E_f \top$.

We apply the above algorithm for $E_f \top$ to $M_\varphi$. 
Büchi automata

Definition:

A Büchi automaton (BA) is a tuple $A = (Q, \Sigma, I, T, F)$ where

- $Q$: finite set of states
- $\Sigma$: finite set of labels
- $I \subseteq Q$: set of initial states
- $T \subseteq Q \times \Sigma \times Q$: set of transitions (non-deterministic)
- $F \subseteq Q$: set of final (repeated) states

Run: $\rho = q_0, a_0, q_1, a_1, q_2, a_2, q_3, \ldots$ with $(q_i, a_i, q_{i+1}) \in T$ for all $i \geq 0$.

$\rho$ is initial if $q_0 \in I$.

$\rho$ is final (successful) if $q_i \in F$ for infinitely many $i$'s.

$\rho$ is accepting if it is both initial and final.

$L(A) = \{a_0a_1a_2\ldots \in \Sigma^\omega \mid \exists \rho = q_0, a_0, q_1, a_1, q_2, a_2, q_3, \ldots \text{ accepting run}\}$

A language $L \subseteq \Sigma^\omega$ is $\omega$-regular if it can be accepted by some Büchi automaton.
Büchi automata

Properties

Büchi automata are closed under union, intersection, complement.

- Union: trivial
- Intersection: easy (exercise)
- Complement: difficult

Let $L$ be the language recognized by the automaton below.

Any non deterministic Büchi automaton for $\Sigma^\omega \setminus L$ has at least $2^n$ states.
Theorem: Büchi

Let $L \subseteq \Sigma^\omega$ be a language. The following are equivalent:

- $L$ is $\omega$-regular
- $L$ is $\omega$-rational, i.e., $L$ is a finite union of languages of the form $L_1 \cdot L_2^\omega$ where $L_1, L_2 \subseteq \Sigma^+$ are rational.
- $L$ is MSO-definable, i.e., there is a sentence $\varphi \in \text{MSO}_\Sigma(\prec)$ such that $L = L(\varphi) = \{w \in \Sigma^\omega | w \models \varphi\}$.

Exercises:

1. Construct a BA for $L(\varphi)$ where $\varphi$ is the FO$_\Sigma(\prec)$ sentence

   $$(\forall x, (P_a(x) \rightarrow \exists y > x, P_a(y))) \rightarrow (\forall x, (P_b(x) \rightarrow \exists y > x, P_c(y)))$$

2. Given BA for $L_1 \subseteq \Sigma^\omega$ and $L_2 \subseteq \Sigma^\omega$, construct BA for

   $\text{next}(L_1) = \Sigma \cdot L_1$

strict − until$(L_1, L_2) = \{uv \in \Sigma^\omega | u \in \Sigma^+ \land v \in L_2 \land$

   $u''v \in L_1 \text{ for all } u', u'' \in \Sigma^+ \text{ with } u = u'u''\}$
Generalized Büchi automata

Definition: final condition on states or on transitions

\( A = (Q, \Sigma, I, T, F_1, \ldots, F_n) \) with \( F_i \subseteq Q \).

An infinite run \( \sigma \) is final (successful) if it visits infinitely often each \( F_i \).

\( A = (Q, \Sigma, I, T, T_1, \ldots, T_n) \) with \( T_i \subseteq T \).

An infinite run \( \sigma \) is final if it uses infinitely many transitions from each \( T_i \).

Example: Infinitely many \( a \)'s and infinitely many \( b \)'s

Theorem:
1. GBA and BA have the same expressive power.
2. Checking whether a BA or GBA has an accepting run is NLOGSPACE-complete.
Unambiguous, Complete, Prophetic (G)BA

**Definition:** Unambiguous, Complete, Prophetic Büchi automata

A BA or GBA $\mathcal{A}$ is **unambiguous** if every word has at most one accepting run in $\mathcal{A}$.
A BA or GBA $\mathcal{A}$ is **complete** if every word has at least one accepting run in $\mathcal{A}$.
A BA or GBA $\mathcal{A}$ is **prophetic** if every word has exactly one final run in $\mathcal{A}$.

Rem: when $I = Q$ then accepting $=$ final.
Hence, when $I = Q$ then prophetic $=$ unambiguous and complete.

**Examples:** Unambiguous, Complete, Prophetic

- Finitely many $a$’s.
- $G(a \rightarrow F b)$ with $\Sigma = \{a, b, c\}$.

**Proposition:**
- Prophetic (G)BA are closed under union, intersection, complement.
- A trimmed prophetic (G)BA is co-deterministic and co-complete.

**Theorem:** Prophetic Büchi automata (Carton-Michel 2003)

Every $\omega$-regular language can be accepted by a prophetic BA.
**Büchi automata with output**

**Definition: SBT: Synchronous (letter to letter) Büchi transducer**

Let $A$ and $B$ be two alphabets. A synchronous Büchi transducer from $A$ to $B$ is a tuple $\mathcal{A} = (Q, A, I, T, F, \mu)$ where $(Q, A, I, T, F)$ is a Büchi automaton (input) and $\mu : T \to B$ is the output function. It computes the relation

$$\llbracket \mathcal{A} \rrbracket = \{(u, v) \in A^\omega \times B^\omega \mid \exists \rho = q_0, a_0, q_1, a_1, q_2, a_2, q_3, \ldots \text{ accepting run}
    \text{with } u = a_0a_1a_2\ldots \text{ and } v = \mu(\rho),
    \text{i.e., } v = b_0b_1b_2\ldots \text{ with } b_i = \mu(q_i, a_i, q_{i+1}) \text{ for } i \geq 0\}$$

If $(Q, A, I, T, F)$ is unambiguous then $\llbracket \mathcal{A} \rrbracket : A^\omega \to B^\omega$ is a (partial) function, in which case we also write $\llbracket \mathcal{A} \rrbracket (u) = v$ for $(u, v) \in \llbracket \mathcal{A} \rrbracket$.

We will also use SGBT: synchronous transducers with generalized Büchi acceptance.

**Example: Left shift with $A = B = \{a, b\}$**

![Diagram](attachment:image.png)
Composition of Büchi transducers

Definition: Composition

Let $A$, $B$, $C$ be alphabets.
Let $A = (Q, A, I, T, (F_i)_i, \mu)$ be an SGBT from $A$ to $B$.
Let $A' = (Q', B, I', T', (F'_j)_j, \mu')$ be an SGBT from $B$ to $C$.
Then $A \cdot A' = (Q \times Q', A, I \times I', T'', (F_i \times Q')_i, (Q \times F'_j)_j, \mu'')$ defined by:

$$
\begin{align*}
(p \xrightarrow{a/b} q \text{ in } A \text{ and } p' \xrightarrow{b/c} q' \text{ in } A') \\
(p, p') \xrightarrow{a/c} (q, q') \text{ in } A \cdot A'
\end{align*}
$$

is an SGBT from $A$ to $C$.
When the transducers define functions, we also denote the composition by $A' \circ A$.

Proposition: Composition

1. We have $[A \cdot A'] = [A] \cdot [A']$.
2. If $(Q, A, I, T, (F_i)_i)$ and $(Q', B, I', T', (F'_j)_j)$ are unambiguous (resp. complete, prophetic) then $(Q \times Q', A, I \times I', T'', (F_i \times Q')_i, (Q \times F'_j)_j)$ is also unambiguous (resp. complete, prophetic), and
   $\forall u \in A^\omega$ we have $[A' \circ A](u) = [A']( [A](u))$. 
Product of Büchi transducers

Definition: Product

Let \( A, B, C \) be alphabets.

Let \( \mathcal{A} = (Q, A, I, T, (F_i)_i, \mu) \) be an SGBT from \( A \) to \( B \).

Let \( \mathcal{A}' = (Q', A, I', T', (F'_j)_j, \mu') \) be an SGBT from \( A \) to \( C \).

Then \( \mathcal{A} \times \mathcal{A}' = (Q \times Q', A, I \times I', T'', (F_i \times Q')_i, (Q \times F'_j)_j, \mu'') \) defined by:

\[
\begin{align*}
    p \xrightarrow{a/b} q \text{ in } \mathcal{A} \text{ and } p' \xrightarrow{a/c} q' \text{ in } \mathcal{A}' \\
    (p, p') \xrightarrow{a/(b,c)} (q, q') \text{ in } \mathcal{A} \cdot \mathcal{A}'
\end{align*}
\]

is an SGBT from \( A \) to \( B \times C \).

Proposition: Product

We identify \((B \times C)^\omega\) with \( B^\omega \times C^\omega \).

1. We have \( [\mathcal{A} \times \mathcal{A}'] = \{(u, v, v') \mid (u, v) \in [\mathcal{A}] \text{ and } (u, v') \in [\mathcal{A}']\} \).

2. If \((Q, A, I, T, (F_i)_i)\) and \((Q', A, I', T', (F'_j)_j)\) are unambiguous (resp. complete, prophetic) then \((Q \times Q', A, I \times I', T'', (F_i \times Q')_i, (Q \times F'_j)_j)\) is also unambiguous (resp. complete, prophetic), and \(\forall u \in A^\omega\) we have \( [\mathcal{A} \times \mathcal{A}'](u) = ([\mathcal{A}](u), [\mathcal{A}'](u)) \).
Subalphabets of $\Sigma = 2^{\text{AP}}$

**Definition:**

For a propositional formula $\xi$ over $\text{AP}$, we let $\Sigma_\xi = \{ a \in \Sigma \mid a \models \xi \}$. For instance, for $p, q \in \text{AP}$,

- $\Sigma_p = \{ a \in \Sigma \mid p \in a \}$ and $\Sigma_{\neg p} = \Sigma \setminus \Sigma_p$
- $\Sigma_{p \land q} = \Sigma_p \cap \Sigma_q$ and $\Sigma_{p \lor q} = \Sigma_p \cup \Sigma_q$
- $\Sigma_{p \land \neg q} = \Sigma_p \setminus \Sigma_q$ ...

**Notation:**

In automata, $s \xrightarrow{\xi} s'$ stands for the set of transitions $\{s\} \times \Sigma_\xi \times \{s'\}$.

**Example:** $G(p \rightarrow F q)$

![Diagram](attachment:image.png)
Semantics of $\text{LTL}$ with sequential functions

Definition: Semantics of $\varphi \in \text{LTL}(\text{AP, SU, SS})$

Let $\Sigma = 2^\text{AP}$ and $\mathbb{B} = \{0, 1\}$.

Define $[\varphi] : \Sigma^\omega \rightarrow \mathbb{B}^\omega$ by $[\varphi](u) = b_0 b_1 b_2 \cdots$ with $b_i = \begin{cases} 1 & \text{if } u, i \models \varphi \\ 0 & \text{otherwise.} \end{cases}$

Example:

$[p \text{ SU } q](\emptyset \{q\}\{p\}\emptyset \{p\}\{p\}\emptyset \{p\}\{p,q\}\emptyset^\omega) = 1001110110^\omega$

$[X p](\emptyset \{q\}\{p\}\emptyset \{p\}\{p\}\emptyset \{p\}\{p,q\}\emptyset^\omega) = 0101100110^\omega$

$[F p](\emptyset \{q\}\{p\}\emptyset \{p\}\{p\}\emptyset \{q\}\emptyset \{p\}\{p,q\}\emptyset^\omega) = 1111111110^\omega$

The aim is to compute $[\varphi]$ with synchronous Büchi transducers (actually, SGBT).

For past formulas, we use deterministic and complete GBA.

For future formulas, we use prophetic GBA.
Prophetic Büchi automaton for $U$ and $SU$

Example: A prophetic BA

![Diagram of a prophetic Büchi automaton]

Lemma: The BA is prophetic

For all $u = a_0a_1a_2\cdots \in \Sigma^\omega$, there is a unique final run $\rho = s_0, a_0, s_1, a_1, s_2, a_2, s_3, \ldots$ of $A$ on $u$.

The run $\rho$ satisfies for all $i \geq 0$, $s_i = \begin{cases} 1 & \text{if } u, i \models q \\ 2 & \text{if } u, i \models \neg q \land (p \cup q) \\ 3 & \text{if } u, i \models \neg(p \cup q) \end{cases}$
Synchronous Büchi transducer for $U$ and $SU$

Example:

SBT for $[[p \ U \ q]]$: 

SBT for $[[p \ SU \ q]]$: 
Special cases of Until: Future and Next

Example: \( F q = \top U q \) and \( X q = \bot SU q \)

Exercise: Give SBT’s for the following formulae:
\[
SF q, \ SG q, \ p \ SR q, \ p \ SS q, \ Y q, \ G q, \ p \ R q, \ p \ S q, \ G(p \rightarrow F q).
\]
Composition and product of SBTs

To compute an SBT for $[\varphi \SU \psi]$, we use composition and product.

Let $f_{SU}: (B \times B)^\omega \rightarrow B^\omega$ be the function defined by

$$f_{SU} ((a_0, b_0)(a_1, b_1)(a_2, b_2) \cdots) = c_0c_1c_2 \cdots$$

when for all $i \geq 0$ we have $c_i = 1$ iff $\exists k > i$, $b_k = 1 \land \forall i < j < k$, $a_j = 1$.

We identify $(B \times B)^\omega$ and $B^\omega \times B^\omega$ and we get for all $w \in \Sigma^\omega$

$$[\varphi \SU \psi](w) = f_{SU}([\varphi](w), [\psi](w))$$

Therefore,

$$A_{\varphi SU \psi} = A_{SU} \circ (A_\varphi \times A_\psi)$$
From LTL to Büchi automata

Definition: SBT for LTL modalities

- $A_T$ from $\Sigma$ to $\mathbb{B} = \{0, 1\}$: 
  - $\circlearrowright 0 \xrightarrow{\Sigma} 1$

- $A_p$ from $\Sigma$ to $\mathbb{B} = \{0, 1\}$: 
  - $\circlearrowright 0 \xrightarrow{p} 1$
  - $\circlearrowleft \neg p \xrightarrow{0} 0$

- $A_\neg$ from $\mathbb{B}$ to $\mathbb{B}$: 
  - $\circlearrowright 0 \xrightarrow{0} 1$
  - $\circlearrowleft 1 \xrightarrow{1} 0$

- $A_\lor$ from $\mathbb{B}^2$ to $\mathbb{B}$: 
  - $\circlearrowright 0 \xrightarrow{0, 0} 0$
  - $\circlearrowleft 1, 0 \xrightarrow{1, 0} 1$
  - $\circlearrowright 0, 1 \xrightarrow{0, 1} 1$
  - $\circlearrowleft 1, 1 \xrightarrow{1, 1} 1$

- $A_\land$ from $\mathbb{B}^2$ to $\mathbb{B}$: 
  - $\circlearrowright 0 \xrightarrow{0, 0} 0$
  - $\circlearrowleft 1, 0 \xrightarrow{1, 0} 0$
  - $\circlearrowright 0, 1 \xrightarrow{0, 1} 1$
  - $\circlearrowleft 1, 1 \xrightarrow{1, 1} 1$
From LTL to Büchi automata

Definition: SBT for LTL modalities (cont.)

- $A_{SU}$ from $\mathbb{B}^2$ to $\mathbb{B}$: Prophetic

- $A_{SS}$ from $\mathbb{B}^2$ to $\mathbb{B}$: Deterministic & Complete
  Not prophetic
From LTL to Büchi automata

**Definition:** Translation from LTL to SGBT

For each \( \xi \in \text{LTL}(\text{AP}, \text{SU}, \text{SS}) \) we define inductively an SGBT \( A_\xi \) as follows:

- \( A_\top \) and \( A_p \) for \( p \in \text{AP} \) are already defined
- \( A_{\neg \varphi} = A_{\neg} \circ A_\varphi \)
- \( A_{\varphi \lor \psi} = A_{\lor} \circ (A_\varphi \times A_\psi) \)
- \( A_{\varphi \text{SS} \psi} = A_{\text{SS}} \circ (A_\varphi \times A_\psi) \)
- \( A_{\varphi \text{SU} \psi} = A_{\text{SU}} \circ (A_\varphi \times A_\psi) \)

**Theorem:** Correctness of the translation

For each \( \xi \in \text{LTL}(\text{AP}, \text{SU}, \text{SS}) \), we have \( [A_\xi] = [\xi] \) and \( A_\xi \) is unambiguous.
Moreover, the number of states of \( A_\xi \) is at most \( 2|\xi|_{\text{SS}} \cdot 3|\xi|_{\text{SU}} \)
the number of acceptance conditions is \( |\xi|_{\text{SU}} \)
where \( |\xi|_{\text{SS}} \) (resp. \( |\xi|_{\text{SU}} \)) is the number of SS (resp. SU) occurring in \( \xi \).

**Remark:**

- If a subformula \( \varphi \) occurs several times in \( \xi \), we only need one copy of \( A_\varphi \).
- We may also use automata for other modalities: \( A_X \) (2 states), \( A_U \), . . .
Useful simplifications

Reducing the number of temporal subformulae

\[(X \varphi) \land (X \psi) \equiv X(\varphi \land \psi) \quad (X \varphi) \mathbin{SU} (X \psi) \equiv X(\varphi \mathbin{SU} \psi)\]
\[(G \varphi) \land (G \psi) \equiv G(\varphi \land \psi) \quad GF \varphi \lor GF \psi \equiv GF(\varphi \lor \psi)\]
\[(\varphi_1 \mathbin{SU} \psi) \land (\varphi_2 \mathbin{SU} \psi) \equiv (\varphi_1 \land \varphi_2) \mathbin{SU} \psi \quad (\varphi \mathbin{SU} \psi_1) \lor (\varphi \mathbin{SU} \psi_2) \equiv \varphi \mathbin{SU} (\psi_1 \lor \psi_2)\]

Merging equivalent states

Let \(A = (Q, \Sigma, I, T, (F_i)_i, \mu)\) be an SGBT and \(s_1, s_2 \in Q\).
We can merge \(s_1\) and \(s_2\) if they satisfy the same final conditions:

\[s_1 \in F_i \iff s_2 \in F_i \quad \text{for all } i\]

and they have the same outgoing transitions: \(\forall a \in \Sigma, \forall s \in Q,\)

\[\tau_1 = (s_1, a, s) \in T \iff \tau_2 = (s_2, a, s) \in T \quad \text{and} \quad \mu(\tau_1) = \mu(\tau_2)\]
Other constructions

- Tableau construction. See for instance [16, Wolper 85]
  + : Easy definition, easy proof of correctness
  + : Works both for future and past modalities
  − : Inefficient without strong optimizations

- Using Very Weak Alternating Automata [17, Gastin & Oddoux 01].
  + : Very efficient
  − : Only for future modalities
  Online tool: http://www.lsv.ens-cachan.fr/~gastin/ltl2ba/

- Using reduction rules [7, Demri & Gastin 10].
  + : Efficient and produces small automata
  + : Can be used by hand on real examples
  − : Only for future modalities

- The domain is still very active.

Satisfiability for LTL over \((\mathbb{N}, <)\)

Let \(\text{AP}\) be the set of atomic propositions and \(\Sigma = 2^{\text{AP}}\).

**Definition: Satisfiability problem**

- **Input:** A formula \(\varphi \in \text{LTL}(\text{AP}, \text{SU}, \text{SS})\)
- **Question:** Existence of \(w \in \Sigma^\omega\) and \(i \in \mathbb{N}\) such that \(w, i \models \varphi\).

**Definition: Initial Satisfiability problem**

- **Input:** A formula \(\varphi \in \text{LTL}(\text{AP}, \text{SU}, \text{SS})\)
- **Question:** Existence of \(w \in \Sigma^\omega\) such that \(w, 0 \models \varphi\).

Remark: \(\varphi\) is satisfiable iff \(\text{F} \varphi\) is *initially* satisfiable.

**Definition: (Initial) validity**

\(\varphi\) is valid iff \(\neg \varphi\) is not satisfiable.

**Theorem [11, Sistla, Clarke 85], [10, Lichtenstein & Pnueli 85]**

The satisfiability problem for LTL is PSPACE-complete.
**Model checking for LTL**

**Definition: Model checking problem**

**Input:** A Kripke structure $M = (S, T, I, AP, \ell)$
A formula $\varphi \in \text{LTL}(AP, SU, SS)$

**Question:** Does $M \models \varphi$?

- **Universal MC:** $M \models \forall \varphi$ if $\ell(\sigma), 0 \models \varphi$ for all initial infinite runs of $M$.
- **Existential MC:** $M \models \exists \varphi$ if $\ell(\sigma), 0 \models \varphi$ for some initial infinite run of $M$.

\[ M \models \forall \varphi \iff M \not\models \exists \neg \varphi \]

**Theorem [11, Sistla, Clarke 85], [10, Lichtenstein & Pnueli 85]**

The Model checking problem for LTL is PSPACE-complete
MC³(SU) ≤ₚ SAT(SU)
[11, Sistla & Clarke 85]

Let $M = (S, T, I, AP, \ell)$ be a Kripke structure and $\varphi \in LTL(AP, SU)$

Introduce new atomic propositions: $AP_S = \{at_s \mid s \in S\}$

Define $AP' = AP \uplus AP_S$ $\Sigma' = 2^{AP'}$ $\pi : \Sigma'^\omega \to \Sigma^\omega$ by $\pi(a) = a \cap AP$.

Let $w \in \Sigma'^\omega$. We have $w \models \varphi$ iff $\pi(w) \models \varphi$

Define $\psi_M \in LTL(AP', X, F)$ of size $O(|M|^2)$ by

$$\psi_M = \left( \bigvee_{s \in I} at_s \right) \land G \left( \bigvee_{s \in S} \left( at_s \land \bigwedge_{t \neq s} \neg at_t \land \bigwedge_{p \in \ell(s)} p \land \bigwedge_{p \notin \ell(s)} \neg p \land \bigvee_{t \in T(s)} X at_t \right) \right)$$

Let $w = a_0 a_1 a_2 \cdots \in \Sigma'^\omega$. Then, $w \models \psi_M$ iff there exists an initial infinite run $\sigma = s_0, s_1, s_2, \ldots$ of $M$ such that $\pi(w) = \ell(\sigma)$ and $a_i \cap AP_S = \{at_{s_i}\}$ for all $i \geq 0$.

Therefore,

$M \models \exists \varphi$ iff $\psi_M \land \varphi$ is initially satisfiable

$M \models \forall \varphi$ iff $\psi_M \land \neg \varphi$ is not initially satisfiable

Remark: we also have $MC^3(X, F) \leq_p SAT(X, F)$. 
Definition: QBF

Input: A formula $\gamma = Q_1 x_1 \cdots Q_n x_n \gamma'$ with $\gamma' = \bigwedge_{1 \leq i \leq m} \bigvee_{1 \leq j \leq k_i} a_{ij}$ (CNF) $Q_i \in \{\forall, \exists\}$ and $a_{ij} \in \{x_1, \neg x_1, \ldots, x_n, \neg x_n\}$.

Question: Is $\gamma$ valid?

Definition:

An assignment of the variables $\{x_1, \ldots, x_n\}$ is a word $v = v_1 \cdots v_n \in \{0, 1\}^n$. We write $v[i]$ for the prefix of length $i$.

Let $V \subseteq \{0, 1\}^n$ be a set of assignments.

- $V$ is valid (for $\gamma'$) if $v \models \gamma'$ for all $v \in V$,
- $V$ is closed (for $\gamma$) if $\forall v \in V, \forall 1 \leq i \leq n$ s.t. $Q_i = \forall$, $\exists v' \in V$ s.t. $v[i-1] = v'[i-1]$ and $v'_i = 1 - v_i$.

Proposition:

$\gamma$ is valid \quad iff \quad \exists V \subseteq \{0, 1\}^n$ s.t. $V$ is nonempty valid and closed
Let \( \gamma = Q_1x_1 \cdots Q_n x_n \bigwedge \bigvee_{1 \leq i \leq m} \bigvee_{1 \leq j \leq k_i} a_{ij} \) with \( Q_i \in \{\forall, \exists\} \) and \( a_{ij} \) literals.

Consider the KS \( M \):

Let \( \psi_{ij} = \begin{cases} 
G(x^f_k \rightarrow s_k \ R \neg a_{ij}) & \text{if } a_{ij} = x_k \\
G(x^t_k \rightarrow s_k \ R \neg a_{ij}) & \text{if } a_{ij} = \neg x_k 
\end{cases} \) and \( \psi = \bigwedge_{i,j} \psi_{ij} \).

Let \( \varphi_i = G(e_{i-1} \rightarrow (\neg s_{i-1} \cup x^t_i) \land (\neg s_{i-1} \cup x^f_i)) \) and \( \varphi = \bigwedge_{i \mid Q_i = \forall} \varphi_i \).

Then, \( \gamma \) is valid iff \( M \models_\exists \psi \land \varphi \).
Theorem: Complexity of LTL

The following problems are PSPACE-complete:

- $\text{SAT}(\text{LTL}(SU, SS))$, $\text{MC}^\forall(\text{LTL}(SU, SS))$, $\text{MC}^\exists(\text{LTL}(SU, SS))$
- $\text{SAT}(\text{LTL}(X, F))$, $\text{MC}^\forall(\text{LTL}(X, F))$, $\text{MC}^\exists(\text{LTL}(X, F))$
- $\text{SAT}(\text{LTL}(U))$, $\text{MC}^\forall(\text{LTL}(U))$, $\text{MC}^\exists(\text{LTL}(U))$
- The restriction of the above problems to a unique propositional variable

The following problems are NP-complete:

- $\text{SAT}(\text{LTL}(F))$, $\text{MC}^\exists(\text{LTL}(F))$
Complexity of $\text{CTL}^*$

**Definition:** Syntax of the Computation Tree Logic $\text{CTL}^*$

$$\varphi ::= \bot \mid p \ (p \in \text{AP}) \mid \neg \varphi \mid \varphi \lor \varphi \mid X \varphi \mid \varphi U \varphi \mid E \varphi \mid A \varphi$$

**Theorem**

The model checking problem for $\text{CTL}^*$ is PSPACE-complete.

**Proof:**

PSPACE-hardness: follows from $\text{LTL} \subseteq \text{CTL}^*$.

PSPACE-easiness: reduction to $\text{LTL}$-model checking by inductive eliminations of path quantifications.
Definition: SAT(CTL*)

Input: A formula $\varphi \in \text{CTL}^*$

Question: Existence of a model $M$ and a run $\sigma$ such that $M, \sigma, 0 \models \varphi$?

Theorem

The satisfiability problem for CTL* is 2-EXPTIME-complete
