

TD 11: Petri Nets

Exercise 1 (Dickson's Lemma). A *quasi-order* (A, \leq) is a set A endowed with a reflexive and transitive ordering relation \leq . A *well quasi order* (wqo) is a quasi order (A, \leq) s.t., for any infinite sequence $a_0 a_1 \dots$ in A^ω , there exist indices $i < j$ with $a_i \leq a_j$.

1. Let (A, \leq) be a wqo and $B \subseteq A$. Show that (B, \leq) is a wqo.
2. Show that $(\mathbb{N} \uplus \{\omega\}, \leq)$ is a wqo.
3. Let (A, \leq) be a wqo. Show that any infinite sequence $a_0 a_1 \dots$ in A^ω embeds an infinite increasing subsequence $a_{i_0} \leq a_{i_1} \leq a_{i_2} \leq \dots$ with $i_0 < i_1 < i_2 < \dots$.
4. Let (A, \leq_A) and (B, \leq_B) be two wqo's. Show that the cartesian product $(A \times B, \leq_\times)$, where the product ordering is defined by $(a, b) \leq_\times (a', b')$ iff $a \leq_A a'$ and $b \leq_B b'$, is a wqo.

Exercise 2 (Coverability Graph). The *coverability problem* for Petri nets is the following decision problem:

Instance: A Petri net $\mathcal{N} = \langle P, T, F, W, m_0 \rangle$ and a marking m_1 in \mathbb{N}^P .

Question: Does there exist m_2 in $\text{reach}_{\mathcal{N}}(m_0)$ such that $m_1 \leq m_2$?

For 1-safe Petri nets, coverability coincides with reachability, and is thus PSPACE-complete.

One way to decide the general coverability problem is to use Karp and Miller's coverability graph (see the lecture notes). Indeed, we have the equivalence between the two statements:

- i.* there exists m_2 in $\text{reach}_{\mathcal{N}}(m_0)$ such that $m_1 \leq m_2$, and
- ii.* there exists m_3 in $\text{CoverabilityGraph}_{\mathcal{N}}(m_0)$ such that $m_1 \leq m_3$.

1. In order to prove that *(i)* implies *(ii)*, we will prove a stronger statement: for a marking m in $(\mathbb{N} \uplus \{\omega\})^P$, write $\Omega(m) = \{p \in P \mid m(p) = \omega\}$ for the set of ω -places of m .

Show that, if $m_0 \xrightarrow{\mathcal{N}} m_2$ in the Petri net \mathcal{N} for some u in T^* , then there exists m_3 in $(\mathbb{N} \uplus \{\omega\})^P$ such that $m_2(p) = m_3(p)$ for all p in $P \setminus \Omega(m_3)$ and $m_0 \xrightarrow{G} m_3$ in the coverability graph.

2. Let us prove that *(ii)* implies *(i)*. The idea is that we can find reachable markings that agree with m_3 on its finite places, and that can be made arbitrarily high on its ω -places. For this, we need to identify the graph nodes where new ω values were introduced, which we call ω -nodes.

- (a) The *threshold* $\Theta(u)$ of a transition sequence u in T^* is the minimal marking m in \mathbb{N}^P s.t. u is enabled from m . Show how to compute $\Theta(u)$. Show that $\Theta(u \cdot v) \leq \Theta(u) + \Theta(v)$ for all u, v in T^* .
- (b) Recall that an ω value is introduced in the coverability graph thanks to Algorithm 1.

```

1 repeat
2   saved ← m';
3   foreach m'' ∈ V s.t. ∃v ∈ T*, m''  $\xrightarrow{v}_G$  m do
4     if m'' < m' then
5       | m' ← m' + ((m' - m'') · ω)
6     end
7   end
8 until saved = m';
9 return m'

```

Algorithm 1: ADDOMEGAS(m, m', V)

We consider a call to ADDOMEGAS(m, m', V) on line 8 of the COVERABILITYGRAPH algorithm from the course notes, where $m \xrightarrow{t}_N m'$ for t the transition chosen at line 6 of the COVERABILITYGRAPH algorithm.

Let $\{v_1, \dots, v_\ell\}$ be the set of “ vt ” sequences, where v is found on line 3 of ADDOMEGAS(m, m', V). These sequences vt resulted in adding at least one ω value to m' on line 5. Let $w = v_1 \cdots v_\ell$. Show that, for any k in \mathbb{N} , the marking ν_k defined by

$$\nu_k(p) = \begin{cases} m'(p) & \text{if } p \in P \setminus \Omega(m) \\ \Theta(w^k)(p) & \text{if } p \in \Omega(m) \end{cases}$$

allows to fire w^k . How does the marking ν'_k with $\nu_k \xrightarrow{w^k}_N \nu'_k$ compare to ν_k ?

- (c) Prove that, if $m_0 \xrightarrow{u}_G m_3$ for some u in T^* in the coverability graph and m' in $\mathbb{N}^{\Omega(m_3)}$ is a partial marking on the places of $\Omega(m_3)$, then there are
- n in \mathbb{N} ,
 - a decomposition $u = u_1 u_2 \cdots u_{n+1}$ with each u_i in T^* (where the markings μ_i reached by $m_0 \xrightarrow{u_1 \cdots u_i}_G \mu_i$ for $i \leq n$ have new ω values),
 - sequences w_1, \dots, w_n in T^+ ,
 - numbers k_1, \dots, k_n in \mathbb{N} ,

such that $m_0 \xrightarrow{u_1 w_1^{k_1} u_2 \cdots u_n w_n^{k_n} u_{n+1}}_N m_2$ with $m_2(p) = m_3(p)$ for all p in $P \setminus \Omega(m_3)$ and $m_2(p) \geq m'(p)$ for all p in $\Omega(m_3)$.

Exercise 3 (Decidability of Model-checking Action-based LTL).

1. Let \mathcal{N} be Petri net, G its coverability graph, and m some marking in \mathbb{N}^P . An infinite *computation* is a sequence $m_0 m_1 \dots$ in $(\mathbb{N}^P)^\omega$ where for all $i \in \mathbb{N}$, $m_i \rightarrow_{\mathcal{N}} m_{i+1}$ is a transition step. The *effect* $\Delta(u)$ of a transition sequence u in T^* is defined by $\Delta(\varepsilon) = 0^P$ and $\Delta(ut) = \Delta(u) - W(P, t) + W(t, P)$.

Show that there exists an infinite computation s.t. $m \leq m_i$ for infinitely many indices i iff there exists an accessible loop $m' \xrightarrow{v}_G m'$ in G s.t. $m \leq m'$ and $\Delta(v) \geq 0^P$.

2. Show that action-based LTL model-checking is decidable for labeled Petri nets.

Exercise 4 (Rackoff's Algorithm). A rather severe issue with the coverability graph construction is that it can generate a graph of Ackermannian size compared to that of the original Petri net. We show here a much more decent EXPSpace upper bound, which is matched by an EXPSpace hardness proof by Lipton.

Let us fix a Petri net $\mathcal{N} = \langle P, T, F, W, m_0 \rangle$. We consider *generalized markings* in \mathbb{Z}^P . A *generalized computation* is a sequence $\mu_1 \dots \mu_n$ in $(\mathbb{Z}^P)^*$ such that, for all $1 \leq i < n$, there is a transition t in T with $\mu_{i+1}(p) = \mu_i(p) - W(p, t) + W(t, p)$ for all $p \in P$ (i.e. we do not enforce enabling conditions). For a subset I of P , a generalized sequence is *I-admissible* if furthermore $\mu_i(p) \geq W(p, t)$ for all p in I at each step $1 \leq i < n$. For a value B in \mathbb{N} , it is *I-B-bounded* if furthermore $\mu_i(p) < B$ for all p in I at each step $1 \leq i \leq n$. A generalized sequence is an *I-covering* for m_1 if $\mu_1 = m_0$ and $\mu_n(p) \geq m_1(p)$ for all p in I .

Thus a computation is a P -admissible generalized computation, and a P -admissible P -covering for m_1 answers the coverability problem.

For a Petri net $\mathcal{N} = \langle P, T, F, W, m_0 \rangle$ and a marking m_1 in \mathbb{N}^P , let $\ell(\mathcal{N}, m_1)$ be the length of the shortest P -admissible P -covering for m_1 in \mathcal{N} if one exists, and otherwise $\ell(\mathcal{N}, m_1) = 0$. For L, k in \mathbb{N} , define

$$M_L(k) = \sup\{\ell(\mathcal{N}, m_1) \mid |P| = k, \max_{p \in P, t \in T} W(p, t) + \max_{p \in P} m_1(p) \leq L\}$$

the maximal $\ell(\mathcal{N}, m_1)$ over *all* Petri nets \mathcal{N} of dimension k and all markings m_1 to cover, under some restrictions on incoming weights $W(p, t)$ in \mathcal{N} and values in m_1 .

1. Show that $M_L(0) \leq 1$.
2. We want to show that

$$M_L(k) \leq (L \cdot M_L(k-1))^k + M_L(k-1)$$

for all $k \geq 1$. To this end, we prove that, for every marking m_1 in \mathbb{N}^P for a Petri net \mathcal{N} with $|P| = k$,

$$\ell(\mathcal{N}, m_1) \leq (L \cdot M_L(k-1))^k + M_L(k-1). \quad (*)$$

Let

$$B = M_L(k-1) \cdot \max_{p \in P, t \in T} W(p, t) + \max_{p \in P} m_1(p).$$

and suppose that there exists a P -admissible P -covering $w = \mu_1 \cdots \mu_n$ for m_1 in \mathcal{N} .

- (a) Show that, if w is P - B -bounded, then $(*)$ holds.
 - (b) Assume the contrary: we can split w as $w_1 w_2$ such that w_1 is P - B -bounded and w_2 starts with a marking μ_j with a place p such that $\mu_j(p) \geq B$. Show that $(*)$ also holds.
3. Show that $M_L(|P|) \leq L^{(3 \cdot |P|)!}$ for $L \geq 2$.
 4. Given a Petri net $\mathcal{N} = \langle P, T, W, m_0 \rangle$ and a marking m_1 , set $L = 2 + \max_{p \in P} m_1(p) + \max_{p \in P, t \in T} W(p, t)$. Assuming that the size n of the instance (\mathcal{N}, m_1) of the coverability problem is more than

$$\max(\log L, |P|, \max_{p \in P, t \in T} \log W(t, p)),$$

deduce that we can guess a P -admissible P -covering for m_1 of length at most $2^{2^{c \cdot n \log n}}$ for some constant c . Conclude that the coverability problem can be solved in EXPSPACE.
